

## ABSTRACT

Gene Expression Profiling to Understand the Alterations in the Monocyte Compartment  
of Pediatric Systemic Lupus Erythematosus

Pinakeen Shankarbhai Patel, Ph.D.

Mentors: Virginia Pascual, M.D.  
Jacques Banchereau, Ph.D.

Blood monocytes from SLE patients display DC function, as they are able to induce the proliferation of allogeneic T cells. Furthermore, sera from SLE patients induce healthy monocytes to differentiate into DCs. This DC-inducing property is in part due to the presence of type-I IFNs in SLE sera, as well as other, yet uncharacterized factors. To understand these alterations, we performed a thorough phenotypic analysis and gene expression profiling of monocytes from children with active, newly diagnosed and untreated disease. Phenotypic analysis of freshly isolated SLE blood monocytes revealed a modest expansion of CD14<sup>high</sup>CD16+ cells and an otherwise lack of expression of molecules related to DC function. Further characterization of a fraction of SLE monocytes inducing allogeneic T cell proliferation revealed that upon contact with T cells, SLE monocytes secrete proinflammatory cytokines such as IL-1 and IL-6 and do upregulate expression of innate immunity receptors involved in DC differentiation and molecules responsible for antigen presentation. To recapitulate the initial events leading

to monocyte differentiation in this disease, we studied the effects of SLE serum on healthy monocyte at the transcriptional and protein levels. These studies revealed the upregulation of expression on these cells of chemokine receptor such as CX3CR1 and CCR7, which may lead to the migration of blood monocytes to inflammed tissues and/or secondary lymphoid organs respectively *in vivo*. There, contact with T cells would lead to the acquisition of antigen presenting function and skewing from tolerogenic to immunogenic responses.

Gene Expression Profiling to Understand the Alterations in the Monocyte Compartment  
of Pediatric Systemic Lupus Erythematosus

## LIST OF ABBREVIATIONS

IFNs	Interferons
IL	Interleukin
ACR	American college of Rheumatology
ANAs	Antinuclear antibodies
BAFF	B cell-activating factor
BCR	B cell receptor
CCL19	Chemokine ligand 19
CCL21	Chemokine ligand 21
CCR7	Chemokine receptor 7
CFSE	Carboxy fluorescein succinimidyl ester
CNS	Central nervous system
CTLA-4	Cytotoxic T lymphocyte-associated 4
CX3CR1	Chemokine, CX3C motif, receptor 1
CXCL10	Chemokine, CXC motif, ligand 10
CXCL11	Chemokine, CXC motif, ligand 11
CXCL9	Chemokine, CXC motif, ligand 9
CXCR3	Chemokine, CX3C motif, receptor 3
DCs	Dendritic cells
DILE	Drug-induced lupus erythematosus
dsDNA	Double stranded DNA

EBNA-1	Epstein-Barr nuclear antigen 1
EBV	Epstein-Barr virus
EMG	Electromyogram
FCS	Fetal calf serum
GSMA	Genome scale meta analysis
HLA	Human leukocyte antigen
IBM	Inclusion body myositis
ICs	Immune complexes
IDDM	Insulin dependent diabetes mellitus
IFNAR1	Interferon-apha receptor 1
IFNAR2	Interferon-apha receptor 2
IIMs	Idipathic inflammatory myopathies
IRF	Interferon regulatory factor
IRF5	Interferon regulatory factor 95
IRF9	Interferon regulatory factor 9
ISGF3	Interferon stimulated gene factor 3
ISREs	Interferon stimulated response elements
ITIM	Immunoreceptor tyrosine-based inhibitory motif
IV	Intravenous
JAK1	Janus activated kinase 1
JAKs	Janus activated kinases
LPS	Lipopolysachharide
MAC	Membrane attack complex

MDA5	Melanoma differentiation associated gene 5
MHC	Major histocompatibility complex
MLR	Mixed lymphocyte reaction
MxA	Myxovirus resistance 1
NKT cell	Natural killer T cells
NOD	Nucleotide binding oligomerization domain
NSAIDs	Non-steroidal anti-inflammatory drugs
NZB	New Zealand black
NZW	New Zealand white
PAMPs	Pathogen associated membrane proteins
PBMCs	Peripheral blood mononuclear cells
PBS	Phosphate buffered saline
pDC	Plasmacytoid dendritic cell
PD-1	Programmed cell death 1
PGE2	Prostaglandin E2
PRR	Pattern recognition receptors
PTPN22	Protein tyrosine phosphatase, non receptor-type, 22
RAG	Recombination-activating gene
RANK	Receptor activator of NF-Kappa-B
RANKL	Receptor activator of NF-Kappa-B ligand
RIN	RNA integration number
RUNX1	Runt-related transcription factor 1
SLAM	Signaling lymphocytic activation molecule

SLC	Secondary lymphoid-tissue chemokine
SLE	Systemic lupus erythematosus
SLEDAI	Systemic lupus erythematosus disease activity index
snRNP	Small nuclear ribonucleoprotein
SS	Sjogren's syndrome
STAT1	Signal transducer and activator of transcription 1
STAT2	Signal transducer and activator of transcription 2
Tfh	Follicular helper T cells
Th1	Helper T cells 1
Th2	Helper T cells 2
TLR	Toll-like receptor
TNF	Tumor necrosis factor
TYK2	Tyrosine kinase 2
WBC	White blood count
Yaa	Y-linked autoimmune accelerator

## AKNOWLEDGMENTS

It was a great journey for me to reach this stage in life to finish my Ph.D.. Without helps of following people, it would be impossible for me to stand up here.

I would like to thank my mentors, Dr. Virginia Pascual and Dr. Jacques Banchereau, for giving me this opportunity to work with them, advising me during this process, and nurturing me intellectually.

I would like to thank Dr. Edsel Arce, who has taught me basic techniques in the beginning of my studies. I would like to thank Jeanine for helping me in scientific writing; Vicky and Minning for RNA extraction and labeling of samples; Linda and Benedicte for helping me in various in vitro experiments; Dorothee Stitchweh, Gabriela, and Natalie for patients information; Quynh and Jin from Microarray core for hybridizing samples on microarray chips; Elizabeth and Sebastien for cell sorting and flow cytometry; Lynnette for providing frozen cell fractions; Yaming for ordering buffy coats for experiments; Sandy for Luminex; Amy and Olivier for providing various antibodies; Dorcus for ordering scientific article, and Cindy for taking care of administrative work.

I would like to thank faculties at Baylor Institute for Immunology Research: Dr. A. Karolina Palucka for the guidance on in vitro experiment with monocytes, Dr. Damien Chaussabel for helping in microarray data analysis, Dr. Gerard Zurawski for immune complex isolation, and Dr. SangKon Ho for setting up transmigration experiments.

I would like thank my colleagues including Adam, Benoit, Chun-I, Dorothee, Florence, and Gina for their helps and supports.

I would also like to thank faculty members at Baylor University: Dr. Christopher Kearney and Dr. William Hillis for serving on my dissertation committee and Dr. Bob Kane, Chairman of Institute of Biomedical Studies, for continuous supports throughout these years.

At last, I would like to thank my wife, Kailash, my parents, and all my friends for their unconditional supports throughout these years.

## DEDICATION

To all children who suffer from lupus

## CHAPTER ONE

### Introduction

#### *Role of Interferon*

#### *Background*

Discovered in 1957, the interferons (IFNs) are family of proteins secreted in response to viral and bacterial infections (Borden and others 2007). There are two types of IFNs, Type I and Type II. They belong to the class II family of  $\alpha$ -helical cytokines that includes IFN- $\lambda$ s, IL-10, and several IL-10 homologs including IL-19, IL-20, IL-22, IL-24, and IL-26. Type I IFNs consist of seven classes, including IFN- $\alpha$ , IFN- $\beta$ , IFN- $\epsilon$ , IFN- $\kappa$  IFN- $\omega$ , IFN- $\delta$ , and IFN- $\tau$ . Out of these, IFN- $\delta$  and IFN- $\tau$  are not found in humans, IFN- $\epsilon$  and IFN- $\kappa$  are expressed in the placenta and keratinocytes respectively. Humans have 13 members of functional IFN- $\alpha$  encoded by 14 genes and single member of IFN- $\beta$  (Pestka and others 2004; Theofilopoulos and others 2005). The type II IFN consists of only one member which is IFN- $\gamma$ .

Various cell types such as myeloid dendritic cells (mDCs) can secrete type I IFNs along with plasmacytoid dendritic cells (pDC), which are main producers of Type I IFNs upon virus stimulation (Liu 2005). Secretion of Type-I IFN occurs upon engagement of specific TLRs (TLR4, TLR9) by pathogen associated molecular patterns (PAMPs) expressed by infectious agents, immune complexes (ICs) containing TLR7, 8 and 9 ligands, and other environmental ligands which can recognize by these receptors. TLRs which strongly induce the secretion of type I IFNs include TLR7 and 9 which are

expressed by pDCs, along with TLRs 3 and 4 expressed by myeloid dendritic cells and macrophages. The specific ligands which can induce type I IFN secretion upon ligation with TLRs are dsRNA for TLR3, LPS for TLR4, ssRNA for TLR7 and 8, and unmethylated CpG-DNA for TLR9 (Iwasaki and Medzhitov 2004). There are other pattern recognition receptors (PRR) like RIG-I (retinoic acid-inducible gene I) and MDA5 (melanoma differentiation associated gene 5) which recognize cytosolic uncapped ssRNA containing 5'-triphosphates and poly I:C respectively (Gitlin and others 2006; Hornung and others 2006).

In both TLR dependent and non TLR dependent secretion of type I IFNs, the interferon-regulatory factor (IRF) family of transcription factors plays a central role in driving intracellular signaling cascades (Honda and Taniguchi 2006). Secreted type-I IFNs exert their effect on target cells by binding their two receptor subunits: IFNAR1 and IFNAR2. The IFNAR1 subunit is constitutively associated with tyrosine kinase 2 (TYK2) and the IFNAR2 subunit is associated with Janus activated kinase 1 (JAK1). Binding of type-I IFNs induces the dimerization of both receptor subunits followed by autophosphorylation and activation of associated JAKs. Activation of the JAKs associated with type I IFN receptors leads to tyrosine phosphorylation of STAT1 (signal transducer and activator of transcription 1) and STAT2, and this results into the formation of STAT1-STAT2-IRF9 complexes, which is known as ISGF3 (IFN-stimulated gene factor 3) complexes. These complexes translocate to the nucleus and bind to ISREs (IFN-stimulated response elements) on target genes to initiate their downstream transcription (Platanias 2005).

Type-I IFNs are pleiotropic cytokines and act as an important player in linking innate and adaptive immune responses. IFN $\alpha$ / $\beta$  signaling upregulates IFN- $\gamma$  production by dendritic cells (DCs) and T cells (Brinkmann and others 1993; Montoya and others 2002). IFN $\alpha$ / $\beta$  also enhances the signaling of IL-6 receptors (Mitani and others 2001) and induces the expression of IL-15 (Zhang and others 1998). IFN $\alpha$ / $\beta$  influence many cell subsets in immune system as, they enhance MHC class I and co-stimulatory molecule expression upon activation of dendritic cells (Biron 2001). IFN $\alpha$ / $\beta$  induce the expression of TLR7 on mDCs (Mohty and others 2003). Monocytes represent a major source of precursor DCs under inflammatory conditions, and a combination of IFN $\alpha$ / $\beta$  and GM-CSF drives them to differentiate into DCs (Banchereau and Pascual 2006). IFN- $\alpha$  strongly enhances IL-10-induced differentiation of functional CD4+ T regulatory cells (Tr1) (Levings and others 2001). Recently it has been shown that IFN $\alpha$ / $\beta$  secreted by pDC upon exposure to flu virus induces the differentiation of B cells into plasmablast, the precursors of antibody secreting plasma cells (Jego and others 2003).

As type I IFN play an important role in mounting immune responses against foreign microbes, it may also play a deleterious role in some autoimmune diseases like Systemic Lupus Erythematosus (SLE), Dermatomyositis (DM), Insulin-Dependent Diabetes Mellitus (IDDM), Sjogren's syndrome (SS) and Psoriasis (Banchereau and Pascual 2006; Theofilopoulos and others 2005). This dissertation focuses on the monocyte compartment of pediatric Systemic Lupus Erythematosus patients.

## *Systemic Lupus Erythematosus*

### *History of Systemic Lupus Erythematosus*

The word lupus, which is a Latin word for wolf, was used in medicine from the 13<sup>th</sup> to the 19<sup>th</sup> centuries to describe a dermatitis characterized by recurrent, florid facial ulcerations. In 1872 Kaposi clarified the acute and chronic types of lupus skin diseases. Osler, in 1895, recognized the systemic nature of the disease Libman and Sacks described the cardiac complications of this disease in 1924. Baehr, Klempler, and Schifrin delineated the features of SLE in 1935 (Smith and Cyr 1988).

The demonstration that lupus patients display was possible thanks to the development of ANAs (antinuclear antibodies) indirect immunofluorescence microscopy. Identification of an antibody against dsDNA in patients with SLE led to the concept that its immune complex mediated disease and many pathological features of the disease like glomerulonephritis can be explained from this finding. The fact that lupus patients display hypercomplementemia was described in 1991 by Morgan and colleagues (Morgan and Walport 1991).

In 1979, Hooks and colleagues reported the presence of circulating interferon in patient with SLE (Hooks and others 1979) which was later confirmed in 1982 by Preble and colleagues (Preble and others 1982). The role of type I IFNs in SLE was supported by the observation that when patients with malignancies or chronic hepatitis C are treated with type I IFNs autoimmune symptoms and seroconversion may occur in a fraction of patients (Ronnblom and others 1991). In 1999 Vallin and colleagues showed that SLE serum contains anti DNA ICs which can induce the secretion of type I IFNs when cultured with healthy PBMC (Vallin and others 1999a). Blanco *et. al.* in 2001 proposed

that type I IFNs break tolerance in SLE by inducing the maturation of dendritic cells (Blanco and others 2001). In 2003 Bennett *et al.* and other groups showed expression of type I IFN regulated genes in peripheral blood cells (Baechler and others 2003; Bennett and others 2003).

*Clinical presentation and treatment.* Systemic lupus erythematosus (SLE) is an episodic, multisystem, autoimmune disease characterized by widespread inflammation of blood vessels and connective tissues and the presence of antinuclear antibodies (ANAs), especially antibodies to double stranded DNA (dsDNA) with hypergammaglobulinemia, lymphopenia and multiple immune dysregulations. Signs and symptoms of SLE can show up quickly or may develop slowly. The disease can be mild or severe, with acute phase to chronic in nature. In almost all patients their symptoms flare and then improve or even disappear completely for some period of time. Some of the most common signs and symptoms of lupus are described in Table 1. These disease manifestations usually develop over the course of time rather than all at once.

Table 1. Clinical Symptoms of Systemic Lupus Erythematosus.

Constitutive	Fever, malaise, weight loss
Cutaneous	Butterfly rash, discoid lupus, periungual erythema, photosensitivity, alopecia, mucosal ulcerations
Musculoskeletal	Polyarthralgia and arthritis, tenosynovitis, myopathy, aseptic necrosis
Vascular	Raynaud's phenomenon, livedo reticularis, thrombosis, erythromelalgia, lupus profundus
Cardiac	Pericarditis and effusion, myocarditis, Libman-Sacks endocarditis
Pulmonary	Pleuritis, basilar pneumonitis, atelectasis, hemorrhage
Gastrointestinal	Peritonitis, esophageal dysfunction, colitis
Liver, spleen, nodes	Hepatomegaly, splenomegaly, lymphadenopathy
Neurologic	Organic brain syndrome, seizures, psychosis, chorea, cerebrovascular accident, polyneuritis and peripheral neuropathy, cranial nerve palsies, pseudotumor cerebri
Ocular	Exudates, papilledema, retinopathy
Renal	Glomerulonephritis, nephrotic syndrome, uremia, hypertension

Diagnosis of SLE can be tricky initially as it is an episodic disease; and patients sometimes present with a history of intermittent symptoms like arthritis, pleuritis, and dermatitis that may precede the actual diagnosis by months or even years. In addition, SLE is a multisystem disease, and patients often have signs and symptoms affecting more than one organ system. Typically, however, SLE is characterized by the presence of anti-nuclear antibodies like anti-dsDNA and anti-RNP.

The American college of Rheumatology (ACR) devised a list of criteria to classify SLE patients (Table 2). These measures are used mainly for diagnosis purposes in the clinic. The ACR revised these criteria for the first time in 1982 (Tan and others 1982) and modified them in 1997 (Table 2) (Hochberg 1997). This classification includes eleven criteria, and diagnosis of lupus can be made when a patient presents with four or more.

Treatment of SLE patients depends on the manifestations of disease. Often times an interdisciplinary approach – with a team of rheumatologists, psychologists, nephrologists, dermatologists, nutritionists and other subspecialists - is taken to tackle this disease effectively (Benseler and Silverman 2005).

Typically, non steroidal anti-inflammatory drugs (NSAIDs) are used to manage musculoskeletal symptoms like myalgia and arthritis. Glucocorticoids, such as oral prednisone and IV methylprednisolone to control fever, dermatitis, arthritis, and serositis, in addition to managing patients with severe acute disease such as hemolytic anemia or overwhelming systemic disease with lupus nephritis. Sometimes hydroxychloroquine is used to treat cutaneous disease as an adjunct to glucocorticoids for systemic disease. Finally, immunosuppressive agents, such as oral azathioprine or oral cyclophosphamide,

are used for patients who are either unresponsive to glucocorticoids or develop severe toxicity to these drugs. Cyclosporine or mycophenolate mofetil help manage renal disease; and IV cyclophosphamide and methotrexate are used to deal with resistant CNS, renal, or skin disease and resistant arthritis. Of course, specific treatments must be individualized based on the extent and severity of disease, as well as efficiency of various pharmacologic agents and patient's tolerance to them.

Table 2. Revised ACR Criteria for Classification of SLE.

- 
1. Malar rash  
Fixed erythema, flat or raised, over the malar eminence, tending to spare the nasolabial folds
  2. Discoid rash  
Erythematous raised patches with adherent keratotic scaling and follicular plugging, atropic scarring can occur in older lesions
  3. Photosensitivity  
Skin rash as a result of unusual reaction to sunlight, per history or physician observation
  4. Oral ulcers  
Oral or nasopharyngeal ulceration, usually painless, observed by the physician
  5. Arthritis  
Non-erosive, involving  $\geq 2$  peripheral joints, characterized by tenderness, swelling or effusion
  6. Serositis  
Pleuritis: history of pleuritic pain, rubbing heard by physician or evidence of pleural effusion  
Pericarditis: documented by electrocardiogram, rub or evidence of pericardial effusion
  7. Renal disorders  
Proteinuria  $> 0.5 \text{ g}/24 \text{ h}$  or 3+, persistently  
Cellular cast: red cell, hemoglobin, granular, tubular or mixed
  8. Neurological disorder  
Seizures: in the absence of offending drugs or metabolic derangements  
Psychosis: in the absence of offending drugs or metabolic derangements
  9. Hematological disorder  
Hemolytic anemia  
Leucopenia  $< 4,000/\text{ul}$  on 2 or more occasions  
Lymphopenia  $< 1,500/\text{ul}$  on 2 or more occasions  
Thrombocytopenia  $< 100,000/\text{ul}$  in the absence of offending drug
  10. Immunological disorder  
Elevated anti-DNA antibody  
Positive anti-Smith antibody  
Positive finding of antiphospholipid antibodies based on:  
IgG/IgM anticardiolipins  
Lupus anticoagulant  
False positive serologic test for syphilis, present for at least 6 months
  11. Antinuclear antibody in a raised titer
-

### *Genetic Susceptibility to Human SLE*

It is usually believed that susceptibility to SLE involves the deregulation of multiple genes in conjunction with external factors, as it described by a “threshold liability model” (Wandstrat and Wakeland 2001). According to this model, the disease will occur if the disease liability - interaction of environmental factors with the presence of genetic susceptibility alleles - passes certain threshold. As described in murine models of SLE like the congenic strain NZM2410, multiple susceptibility loci must be inherited to predispose to disease.

Various studies conducted in the past to years show that first, second, and third degree relatives of SLE patients are more susceptible to disease than non-related healthy counterparts (Alarcon-Segovia and others 2005; Deapen and others 1992; Vyse and Kotzin 1998). In twin studies, a concordance rate of 24% to 57% was observed for SLE (Deapen and others 1992). In addition, the degree of family clustering, which is a ratio of the prevalence of SLE in affected family to the prevalence of SLE within the population as a whole is 10-20 (Vyse and Kotzin 1998). Great progress been made in establishing relationship between lupus susceptibility and polymorphisms in various individual genes in humans (Alarcon-Riquelme 2006)

*Linkage studies.* The goal of linkage studies is to identify genomic segments cotransmitted with the disease in families containing two or more affected members (Tsao 2004). Tsao *et. el.* first described the 1q41-42 region on chromosome 1 is associated with SLE. Of interest, this region equivalent to one of the chromosomal regions known to convey SLE susceptibility in mice (Tsao and others 1997). Since then many more regions have been identified which are linked to SLE susceptibility.

Recently Criswell and colleagues performed genome scale meta-analysis (GSMA) to combine linkage results from all genome screens for SLE done until the time of study. They identified genome-wide regions on 6p21.1-q15, 20p11-q13.3 and 16p13-q12.2 significantly associated with SLE susceptibility (Forabosco and others 2006). Fine mapping of these regions led to the candidate genes which might contribute to the onset of SLE. Some of them are going to be discussed in following two sections.

*Susceptibility genes associated with HLA complex.* In 1979, the first genetic association study done in human SLE described association of human leukocyte antigens (HLA) to disease susceptibility (Goldberg and others 1976). The HLA region is located within a 3.6 Mb interval on human chromosome 6p21.3, it encodes more than 200 genes and out of them around 40% are related to immune function (1999). Class II haplotypes containing DRB1 and DQB1 alleles are associated with susceptibility to SLE (Graham and others 2002). In Caucasians HLA-DR2 and HLA-DR3 convey about a two- to three-fold increased risk of developing SLE, and HLA-DR2 and HLA-DR7 increase susceptibility in African-American population (Vyse and Kotzin 1998). Certain haplotypes are also associated with the production of specific antibodies. Specifically, Griffing and colleagues described a strong association between HLA-DRw3 haplotype and anti dsDNA antibodies in SLE patients (Griffing and others 1980). More recently, an association of DR2 haplotypes with production of anti-Sm antibodies and DR3 haplotypes with anti-Ro and anti-La antibodies has been reported (Graham and others 2007).

The MHC class III locus contains genes encoding members of the classical pathway of the complement cascade. Homozygous hereditary deficiency of various

component of this pathway like C1q, C1r, C1s, C4, and C2 is associated with increased susceptibility to SLE (Morgan and Walport 1991). The same region also contains the gene encoding TNF- $\alpha$ , and a -308 promoter polymorphism in the TNF gene is associated with SLE and leads to decrease levels of TNF in patients (Magnusson and others 2001). Interestingly, levels of TNF $\alpha$  may regulate the production of type I IFN as described by Palucka *et.al.* (Palucka and others 2005).

*Susceptibility Genes Outside of the HLA Complex.* Many genes related to immune function outside of the HLA complex may be of interest in studying possible mechanisms of immune dysregulation in lupus. One such gene is PDCD1. PDCD1 is an immunoreceptor of the co-stimulatory receptor family that has immunoreceptor tyrosine-based inhibitory motif (ITIM). It is expressed on the surface of activated T cells and B cell and plays a significant role in maintenance of peripheral tolerance (Nishimura and Honjo 2001). A recent study showed an intronic single nucleotide polymorphism in PDCD1 that is significantly associated with the development of SLE in Europeans and Mexicans. This SNP alters the binding site for the transcription factor RUNX1 (Prokunina and others 2002). Another gene, PTPN22 found at the 1p13 region of chromosome 1 has been associated to lupus. This gene encodes a negative regulator of T-cells signal transduction (Hasegawa and others 2004). A polymorphism at the proximal proline-rich SH3-binding domain of PTPN22 results in an R630W amino acid substitution. This polymorphism is associated with an increased risk of developing SLE in Caucasians (Kyogoku and others 2004).

Another candidate immunoregulatory gene encodes Fc $\gamma$ RIIb, which has an ITIM in its cytoplasmic domain and inhibits tyrosine-based activation signals in different cell

subsets (Hawiger and others 2001). Mice deficient for Fc $\gamma$ RIIb develop autoantibodies and autoimmune glomerulonephritis in a strain-dependent fashion (Bolland and Ravetch 2000). In humans, a polymorphism of Fc $\gamma$ RIIb, Fc $\gamma$ RIIbT<sub>232</sub>, was identified that encodes a substitution from isoleucine to threonine at position 232 within the transmembrane domain. Frequency of homozygosity for this polymorphism is at least double in persons affected with SLE as compared to their healthy counterparts (Floto and others 2005). Polymorphisms at this position in the cytoplasmic domain of Fc $\gamma$ RIIb make it unable to inhibit activatory receptors. Alternatively, activating Fc $\gamma$  receptors, such as Fc $\gamma$ R2A and Fc $\gamma$ R3A, have immunoreceptor tyrosine-based activating motifs (ITAMs) in their cytoplasmic tail which activate the cells when they bind to the Fc portion of antibodies. These receptors play very important roles in the clearance of immune complexes from the blood.

A recent meta-analysis, involving around 17 different studies including 1,405 patients with lupus nephritis, 1,709 SLE patients without nephritis and 2,580 healthy controls, showed significant correlation of Fc $\gamma$ IIa- R/H131 polymorphism to SLE susceptibility in patients from different ethnic background (Karassa and others 2002). Other receptors like Fc $\gamma$ IIIa, which is expressed on NK cells, subsets of monocytes and macrophages, binds to the Fc portion of both IgG1 and IgG3 subclasses. This receptor has two variants, F158 and V158, that differ in phenylalanine or valine amino acids at position 176 in the extracellular domain of the receptor, respectively. V158 homozygous variant binds to Fc portion of IgG1 and IgG3 more avidly than the F158 variant (Koene and others 1997; Wu and others 1997). Recently, a separate meta analysis which included 11 studies and involved 1154 patients with lupus nephritis, 1261 SLE patients

without nephritis, and 1455 controls, showed that the Fc $\gamma$ IIA-V/F158 polymorphism was significantly associated with lupus nephritis (Karassa and others 2003).

Another important player in the clearance of immunecomplexes is the complement system. Very recently it has been shown that a single nucleotide polymorphism in the receptor for the complement component CR2, which expressed on mature B cells and follicular dendritic cells, was significantly associated with susceptibility to SLE (1.54-fold increased risk) (Wu and others 2007). Because it was recently shown that type I IFNs play a prominent role in the pathogenesis of SLE (Banchereau and Pascual 2006), genetic alterations in this pathway are of great interest. When thirteen candidate genes in these pathway were analyzed for 44 SNPs in patients from different ethnic background with SLE, polymorphism in tyrosine kinase 2 (TYK2) and IFN regulatory factor 5 (IRF5) were significantly associated with SLE (Sigurdsson and others 2005); and interestingly, these findings were very recently confirmed (Harley and others 2008). This same report as well as others show that polymorphisms in various genes like BANK1 (a B cell genes), BLK gene encoding B lymphoid tyrosine kinase, ITGAM gene encoding CD11b, ITGAX gene encoding integrin- $\alpha$ , and PXK gene were associated with susceptibility to SLE (Harley and others 2008; Hom and others 2008; Kozyrev and others 2008; Nath and others 2008). A significant gender bias of SLE towards females can possibly be explained by the recent finding regarding association of a SNP in the MECP2 gene which encode methyl-CpG-binding protein 2, to susceptibility to SLE, since this gene is located on chromosome Xq28 and play an important role in epigenetic transcriptional regulation of methylation-sensitive genes (Sawalha and others 2008)

### *Environmental Factors*

Photosensitivity is a hallmark symptom of SLE. Exposure to sunlight is known to exacerbate the systemic disease activity. Specifically, ultraviolet B (UVB) irradiation has multiple effects on the keratinocytes of the skin which are important in lupus pathogenesis, including induction of apoptosis of keratinocytes and expression of soluble intracellular antigens like small nuclear ribonucleoprotein (snRNPs) such as the 52 kD Ro/SS-A on the cell surface. This ectopic expression of intracellular antigens may make them available as immunogens (Casciola-Rosen and others 1994; White and Rosen 2003). It is well known that SLE patients have antibodies against these nuclear antigens, which can form ICs. ICs containing chromatin antigens can bind to plasmacytoid dendritic cells and activate them to secrete type I IFN, therefore closing a pathogenic loop (Lovgren and others 2006).

In addition, various drugs and chemicals have been reported to cause symptoms and laboratory characteristics which closely resemble those of SLE, giving rise to what is known as the “lupus-like syndrome” or as “drug-induced lupus erythematosus (DILE)”. DILE is diagnosed according to: (1) continuous treatment with suspected drug for at least one month or longer, (2) common presenting symptoms: arthralgias, myalgias, malaise, fever, serositis, (3) laboratory profile: anti-histone antibodies, (4) symptoms improve within days or few weeks after discontinuation of the treatment (Sarzi-Puttini and others 2005). The first reported agent associated with DILE was sulfadiazine. Since then over eighty, often commonly prescribed drugs, has been reported to induce DILE. Another chemical which can induce lupus like symptoms is, L-canavanine, a non-protein amino acid in alfalfa sprouts and seeds (Akaogi and others 2006).

Viral infection may also play an important role in the etiology and pathogenesis of DLR. In lupus patients, elevated titres of antibodies against measles, rubella and Epstein-Barr virus (EBV) has been reported (Edwards and Cooper 2006). Since these are common viral infections, increased antibody titres can result from polyclonal B cell activation rather than have a causative role. A strong association of SLE with EBV has been suggested due to increased load of EBV in patients, along with high titres of anti-EBV antibodies. Furthermore, sequence homology between various autoantigens and Epstein-Barr Nuclear Antigen-1 (EBNA-1) have been described (James and others 2006).

### *Immune System Dysregulation*

As described in the previous section, environmental factors acting on individuals with genetic susceptibility can trigger disease. But how this cascade of events starts and

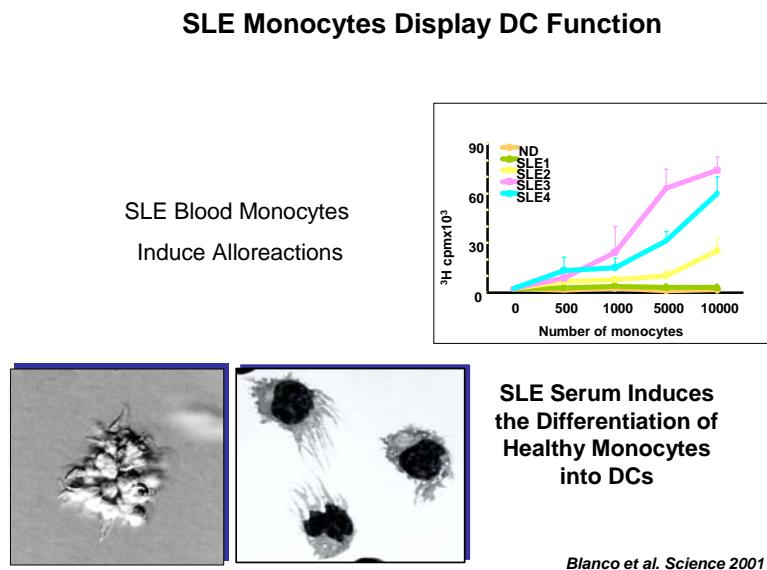

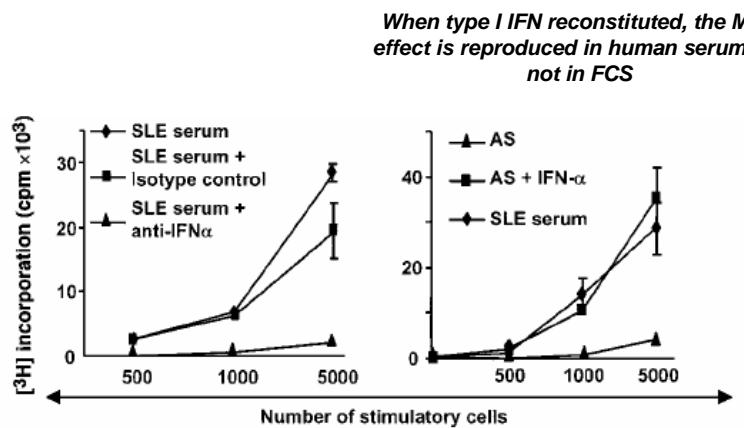

Figure 1. SLE monocytes display DC function. (A) Monocytes from a proportion of SLE patients induce proliferation of allogeneic CD4<sup>+</sup> T cells. (B) SLE patients' serum induces monocytes to differentiate into cells with DC properties. Monocytes cultured with SLE patients' serum (left), but not with autologous serum (right), cluster within 12 to 24 hours, and, within 24 to 72 hours, clustered cells display fine cytoplasmic projections (Giemsa staining, middle).

at what point immune regulation mechanisms fail is not known. Very recently, great progress has been made in understanding how peripheral tolerance breaks. Dendritic cells, which bridge innate and adaptive immunity, induce tolerance when they are immature and incite immune reactions when mature (Banchereau and Steinman 1998; Steinman and others 2003). In SLE patients, monocytes - precursors for dendritic cells - induce CD4 T cells to proliferate (Blanco and others 2001) (Figure 1). This CD4 T cell proliferation-inducing capacity of monocytes from SLE patients is dependent on the presence of type-I interferons in patients' sera, as it can be reproduced by adding lupus sera to healthy monocytes and can be inhibited by adding neutralizing monoclonal antibodies (Figure 2). It's also been shown that type I interferon, which is produced by plasmacytoid dendritic cells (pDC) (Liu 2005; Siegal and others 1999), with the help of IL-6 drive the differentiation of mature B cells to plasma cells (Jego and others 2003; Jego and others 2005). In SLE patients plasmablast cells which are precursors of plasma cells are expanded in the blood (Arce and others 2001). Gene expression profile from the PBMCs of the pediatric SLE patients showed the signature of plasma cells and low density immature neutrophils, which correlated with number of immature neutrophils in PBMCs (Bennett and others 2003).

*Blood B cell alterations in human SLE.* Profound alterations in blood B cell compartments have been described in SLE (Odendahl and others 2000). Conventional naïve and memory B cell numbers are decreased while CD38<sup>+</sup> B cells, which include oligoclonal plasma cell precursors (PCPs), are expanded. SLE blood PCPs display a phenotype similar to that of PCPs found in the blood during secondary immune responses, including isotype-switched and mutated Ig genes (Arce and others 2001).

While these cells are only transiently increased during normal immune responses, they are persistently elevated in children with SLE. Whether these SLE PCPs will become short-lived or long-lived plasma cells is not clear yet. Studies in mice suggest that they may be only short lived.

#### SLE Serum-Induced Monocyte Differentiation into DC is Due to IFN- $\alpha$

*Blanco et al. Science 2001*

Figure 2. Induction of DC differentiation is IFN- $\alpha$  dependent. (A) IFN- $\alpha$  neutralizing antibody (10  $\mu$ g/ml) blocks the induction of DCs by SLE patients' serum. Representative of three experiments. (B) Spiking autologous serum with 100 UI/ml IFN- $\alpha$  results in the induction of monocyte differentiation to DCs as determined by MLR capacity.

*Intrinsic defects in B cell tolerance checkpoints.* Large numbers of developing B cells in the bone marrow and recent emigrants in the blood express self-reactive B cell receptors (BCRs). However, they represent only 5-20% of healthy naïve blood B cells (Wardemann and others 2003), thus suggesting the presence of a major tolerance checkpoint. In SLE patients this checkpoint is defective, as 25-50% of the blood naïve B cells express self-reactive BCRs (Yurasov and others 2005). Further evidence for altered B cell tolerance checkpoints in SLE comes from the analysis of B cells expressing the

VH4-34 gene, which encodes autoantibodies of different specificities (Pascual and Capra 1992). In healthy individuals, VH4-34<sup>+</sup> B cells are excluded during the early stages of the germinal center (GC) reaction before acquiring a centroblast phenotype, thus representing a second checkpoint. In SLE, but not in Rheumatoid Arthritis (RA) patients, VH4-34<sup>+</sup> cells progress through this checkpoint, participate in GC reactions, and are expanded within the post-GC IgG memory and plasma cell compartments (Cappione and others 2005). Although the gene(s) responsible for the control of human B cell tolerance checkpoints in SLE patients are not known, studies in mice have identified potential candidates. For example, the Sle1z/Sle1bz murine lupus susceptibility locus on chromosome 1, which is associated with production of anti-chromatin antibodies, has been shown to impair B cell anergy, receptor revision, and deletion. The Ly108.1 isoform of the Ly108 gene, a member of the SLAM costimulatory family, influences the ability of immature B cells to undergo deletion and RAG reexpression and represents the prime candidate for altering tolerance checkpoints in this model (Kumar and others 2006).

*IFN- $\alpha/\beta$  and B cells.* Through their effect on B cells, IFN- $\alpha/\beta$  directly enhance primary antibody responses to soluble proteins and induce the production of all subclasses of IgG in mice (Le Bon and others 2006). IFN- $\alpha/\beta$  also increases the expression of CD38 (Bennett and others 2003), which is expressed on germinal center B cells and plasma cells (Galibert and others 1996). Furthermore, it promotes the differentiation of mDCs that can directly act on the growth and differentiation of B cells (Dubois and others 1997; Garcia De Vinuesa and others 1999). mDCs trigger B cell growth and differentiation through IL-12 and IL-6 (Dubois and others 1998) as well as

BAFF (Balazs and others 2002; Litinskiy and others 2002; MacLennan and Vinuesa 2002), which is induced by IFN- $\alpha/\beta$  and contributes to the survival of peripheral, including self-reactive B cells (Thien and others 2004).

Virus-stimulated pDCs can induce the maturation of CD40-activated B cells into plasma cells through two cytokines. First, IFN- $\alpha/\beta$  promotes the differentiation of activated B cells into plasmablasts, then IL-6 permits plasmablasts to become antibody-secreting plasma cells (Jego and others 2003). The CD40-L signal required to activate pDCs might be provided by T cells, but other cell types may contribute as CD40-L is expressed by circulating T and B cells in SLE (Desai-Mehta and others 1996).

*TLRs and B cells.* Clinical SLE is preceded by the progressive accumulation of autoantibody specificities up to 9 yr before diagnosis. Anti-nuclear, anti-Ro, anti-La, and anti-phospholipid antibodies appear first, followed by anti-dsDNA antibodies and then anti-Sm and anti-nuclear ribonucleoprotein antibodies (Arbuckle and others 2003). Thus, clinically overt disease develops closer to the time of breakdown of tolerance against DNA and ribonucleoproteins.

The contribution of ICs and TLR signaling to the generation of autoantibodies characteristic of SLE has attracted numerous studies in mice but less is known in humans. In vitro, chromatin-containing IC activate transgenic autoreactive B cells via sequential engagement of the B cell antigen receptor (BCR) and TLR 9 (Leadbetter and others 2002). In vivo, TLR 9 contributes to the development of anti-ds DNA antibodies, as lupus-prone (Fas-deficient) mice that lack TLR 9 on the mixed MRL/B6/129 background fail to generate these antibodies. Yet, the production of cardiolipin and RNA-reactive antibodies and the development of nephritis are not affected in these mice (Christensen

and others 2005). On a different mouse background (B6 mice lacking the inhibitory Fc $\gamma$ RIIb) (Bolland and Ravetch 2000), TLR 9 signaling is required for anti-DNA/polyreactive IgM $^+$  B cells that have escaped central tolerance to switch to pathogenic isotypes (Ehlers and others 2006). Yet, in a different mouse lupus-like model, the pure MRL/lpr, TLR 9 seems to deliver protective signals, as TLR 9 $^{-/-}$  MRL/lpr mice develop more autoantibodies and severe lupus-like disease (Wu and Peng 2006). As discussed earlier, this model seems to be mediated by IFN- $\gamma$  and not IFN- $\alpha\beta$ , as the absence of type-I IFN receptor worsens disease in these mice (Hron and Peng 2004), which is at variance with the NZB model (Santiago-Raber and others 2003).

The contradicting mouse results on the contribution of TLR 9 signaling to SLE pathogenesis have also been reported for Dextran Sulfate Sodium (DSS)-induced Inflammatory Bowel Disease. Thus, TLR 9 ligands protect mice if administered prior to disease induction, but have the opposite effect in mice with established chronic disease (Katakura and others 2005; Obermeier and others 2003). Conclusions drawn from lupus-like models should therefore be extrapolated to humans only with caution. First, the expression of TLR 9 on immune cells differs significantly in mice and humans. Second, the various murine lupus-like models may not faithfully reproduce the human disease. For example, mutations in Fas/Fas-L which are the hallmark of the MRL/lpr/gld models extensively studied as surrogates to human SLE, do not cause this disease in humans. Instead, these mutations give rise to a unique syndrome characterized by lymphoproliferation and autoimmunity that is easy to differentiate from SLE (Worth and others 2006).

TLR 7 signaling also seems to contribute to SLE-like syndrome in mice. As shown for pDCs, ICs containing RNA and RNA-associated autoantigens activate autoreactive B cells in vitro (Lau and others 2005). In vivo, Fc $\gamma$ RIIb -/- mice develop enhanced autoimmunity when crossed to the Y-linked autoimmune accelerator (Yaa) locus (Bolland and others 2002), which harbors a duplication in the TLR 7 gene (Pisitkun and others 2006). Finally, injection of the TLR 7 ligand Imiquimod® increases serum levels of IL-12p70, IFN- $\alpha$  and IL-6 and aggravates lupus nephritis in MRL/lpr mice (Pawar and others 2006). Naturally occurring differences in expression of the TLR 7 gene, as well as environmental factors that induce TLR 7 expression (i.e., IFN- $\alpha\beta$  (Bekeredjian-Ding and others 2005; Mohty and others 2003)) and /or TLR 7 responses, could therefore result in increased pDC and B cell responses to RNA-containing self antigens and contribute to human SLE pathogenesis as well.

*T cells and lupus.* T cell lymphopenia is as common to SLE patients as B cell lymphopenia. Excess of IFN- $\alpha/\beta$  can explain this phenomenon as administration of type I IFNs into new born mice greatly reduced the development of both T and B lymphocytes (Lin and others 1998). In SLE, T cells are altered functionally as both CD4 and CD8 T cells express high amount of ICOS compared to healthy (Yang and others 2005). In the NZM2410 mice model of SLE, mice express Sle1 locus; and CD4 T cells from this mice are hyperproliferative and secrete high amount of cytokines, and provide help to anti-chromatin B cells in order to produce anti-nuclear antibodies (Chen and others 2005). Also, CD4 T cells from the MRL/lpr mice showed lower threshold of activation (Zielinski and others 2005). CD4 $^{+}$  T cells expressing CCR4 infiltrate renal tissue in SLE patients (Yamada and others 2002) and may cause renal tissue damage by cytotoxic

effect via perforin secretion, since secreted perforin is known to be functional as evidenced by its ability to kill monocytes *in vitro* (Kaplan and others 2004).

The role of regulatory T cells, important players in the maintenance of tolerance, in SLE patients is not well understood. Mice depleted of Tregs develop multi-organ autoimmune disease, and some mice develop lupus features like antibodies to dsDNA and glomerulonephritis (Sakaguchi and others 1995). CD4<sup>+</sup>CD25<sup>+</sup> Tregs are reduced in SLE mice as well as in SLE patients (Mudd and others 2006). The suppressive function of CD4<sup>+</sup>CD25<sup>high</sup> Treg is significantly decreased in active SLE patients along with reduced expression of Foxp3 at the RNA and protein level (Valencia and others 2007). Other subsets of T cells, such as follicular B helper T cells (Tfh) which are localized in B cell follicles in lymph node and support the antibody production (Vinuesa and others 2005b) may play an important role in SLE as these cells are expanded in two murine model of SLE: the sanroque mice carrying a mutated ubiquitin ligase (roquin) gene (Vinuesa and others 2005a) and the B6.Sle1.yaa mice carrying a polymorphic cluster encoding SLAM and CD2 in addition to a duplication in TLR (Subramanian and others 2006).

Alteration in the CD8 compartment in SLE patients has been reported very extensively. Despite lymphopenia, active SLE patients have higher number of CD8<sup>+</sup> T cells (Matsushita and others 2000) along with CD8<sup>+</sup> T cells expressing HLA-DR, a marker for activated T cells (Viallard and others 2001). Percentages of CD8<sup>+</sup>DR<sup>+</sup> T cells are most significantly associated with a flare in SLE patients (Blanco and others 2005; Viallard and others 2001). CD8 T cells from SLE patients express higher amount of perforin and granzyme B which correlated with disease activity. Sera from SLE patients

contain high amount of soluble nucleosomes (Amoura and others 1997). SLE CD8 T cells may play a role in this aspect of SLE, as CD8 T cells from SLE patients generate nucleosomes when mixed with target cells *in vitro* (Blanco and others 2005). It has been shown that CD8 T cells infiltrate predominantly the periglomerular areas of the kidney and may cause permanent damage at the site of infiltration (Couzi and others 2007).

*Role of DCs in inducing immune reactions.* Dendritic cells (DCs) play a central role in the immune reactions. They initiate as well as control the immune system by influencing other arms of the immune system. Dendritic cells are professional antigen presenting cells, and they present antigen to both B cells and T cells to initiate the antigen specific adaptive immune response (Banchereau and others 2000; Banchereau and Steinman 1998; Steinman 1991). DCs act as sentinels in all peripheral tissues in their immature state. There are mainly two types of dendritic cells based on their blood precursors: myeloid dendritic cells (mDC), originated from myeloid CD34<sup>+</sup> progenitor cells which include interstitial dendritic cells, and langerhans DC and plasmacytoid dendritic cells (pDC) which may originate from lymphoid progenitor cells.

Microbial infections stimulate DCs to orchestrate a protective function for the immune system. Microbial products trigger DCs to secret large amount of IL-12 (Reis e Sousa and others 1997), and IFN- $\alpha/\beta$  (Dalod and others 2002). Exposure to these cytokines activates other cells in the innate immune system like natural killer (NK) (Fernandez and others 1999) and NKT cells (Fujii and others 2002). Mature DC initiate or prime T cell responses (Inaba and others 1993; Inaba and others 1990) by polarizing it to either Th1 or Th2 responses (Nakahara and others 2006; Pulendran 2004; Soares and others 2007). To control innate and adaptive immunity, DCs must undergo terminal

differentiation and maturation. Maturation can be induced by various agents including microbes and their products. *In vivo*, maturation can be induced by TLR ligation (De Smedt and others 1996; Sparwasser and others 2000) and CD40, a tumor necrosis family member (O'Sullivan and Thomas 2003). *In vitro*, DC maturation can be induced by a cocktail of inflammatory cytokines like IL-1, TNF- $\alpha$ , IL-6 and PGE2, as it has been shown in clinical vaccine trials (Jonuleit and others 1997). Maturation of dendritic cells results in many phenotypic and functional changes, such as increased production and expression of peptide-MHC complexes on the surface (Inaba and others 2000), increased expression of co-stimulatory molecules (Inaba and others 1994) and production of T cell growth factors like IL-2 (Granucci and others 2001) as well as thiols (required for to sustain lymphocyte activation and proliferation (Gmunder and others 1990)) (Angelini and others 2002), chemokines (Sallusto and others 1999), and cytokines (Langenkamp and others 2000). The maturation process triggers peripheral DC migration to the T cell area of lymphoid organs. Upon maturation, DCs upregulate a chemokine receptor, CCR7 (Yoshida and others 1997) and acquire responsiveness to MIP-3 $\beta$  (CCL19) (Dieu and others 1998) and other secondary lymphoid-tissue chemokines (SLC) (CCL21) (Chan and others 1999). CCR7 allows mature DC to leave the inflamed tissues and enter the lymph by transmigrating through lymph vessels (Saeki and others 1999). In the lymphoid organs, mature dendritic cells encounter T cells and receive additional maturation signals from CD40 ligand, RANK/RANKL, 4-1BB and OX40 ligand, they in turn secrete IL-8, fractalkine and other chemokines which attract lymphocytes (Adema and others 1997; Kanazawa and others 1999; Tang and Cyster 1999).

*Role of DC in Immune Tolerance.* Dendritic cells play a role in both central and peripheral tolerance. During the process of intrathymic T cell development, around fifty million cells are generated daily, and 95% of them are lost daily due to positive and negative selection of T cells in the thymus (von Boehmer and others 2003). Cortical and medullary thymic epithelial cells (cTEC and mTECs), thymic dendritic cell, macrophages and thymic B cells express various tissue restricted self-antigens (TRAs) in the context of MHC class II molecules (Kyewski and Klein 2006). Both thymic epithelial cells and thymic DCs can eliminate autoreactive T cells. Thymic dendritic cells are most efficient at deleting T cells during this process (Anderson and others 1998).

Even though central tolerance is efficient, it is not complete. Indeed self-reactive T cells especially those T cells with lower affinity for self-antigens, can escape the negative selection and reach the periphery (Bouneaud and others 2000). Tolerance to those self antigens which do not have access to the thymus needs to be developed (Lo and others 1989). T cells recognizing antigens which are expressed later in the life after formation of the lymphocyte repertoires, as well as those non pathogenic environmental antigens to which body is constantly exposed to, like proteins and natural commensal bacterial flora in gut and intestines, also need to be tolerated (Steinman and Nussenzweig 2002). Dendritic cells play an important role in this process. Indeed, immature myeloid DCs induce tolerance in the steady state (Steinman and Nussenzweig 2002). At this stage, DCs are highly phagocytic and efficiently engulf and process proteins from peripheral tissues including those from dying cells. These DCs then migrate to lymphoid tissues. Thus, DCs loaded with apoptotic material are found in steady-state within Peyer's patches and mesenteric lymph nodes in the gut and (Huang

and others 2000), and in the thoracic lymph nodes from the lung (Vermaelen and others 2001). These DCs then present the processed self-antigens in the absence of costimulatory signals to naïve autoreactive T cells and induce T-cell anergy or deletion (Banchereau and others 2004). Also, immature DCs control peripheral tolerance by inducing the expansion of regulatory T cells (Yamazaki and others 2006). Additionally, plasmacytoid DCs (pDC), induce tolerance against alloantigens through induction of regulatory T cells (Ochando and others 2006).

*Role of DCs in SLE.* Monocytes represent a major source of precursor DCs under inflammatory conditions (Banchereau and Palucka 2005). Thus, GM-CSF allows monocyte activation and other cytokines permit the differentiation into distinct DC subtypes. In particular, IFN- $\alpha/\beta$  together with GM-CSF drive monocytes to become DCs (Luft and others 1998; Paquette and others 1998; Santini and others 2000). Blood monocytes from SLE patients behave like mDCs, as they are able to induce the proliferation of allogeneic CD4 $^{+}$  T cells (Blanco and others 2001). Furthermore, exposure of normal monocytes to SLE serum results in the generation of DCs, suggesting that SLE blood represents a DC-inducing environment. This activity is dependent on IFN- $\alpha$  and correlates with disease activity (Blanco and others 2001). Unabated DC maturation could lead to the activation/expansion of autoreactive T cells which have escaped central tolerance, thus explaining many of the features of the disease (Banchereau and others 2004) (Figure 3).

DCs generated in the presence of sera containing IFN- $\alpha$  from patients with active disease also drive the differentiation of CD8 $^{+}$  T cells toward fully active cytotoxic effector T lymphocytes able to generate nucleosomes (Blanco and others 2005) as well

as granzyme B-dependent unique autoantigen fragments (Casciola-Rosen and others 1999). These novel autoantigens could be captured and presented by mDCs, therefore establishing a self-amplifying loop. Indeed, administration of DC loaded with apoptotic cells consistently triggers autoimmune responses in mice, although clinical autoimmunity only develops in genetically susceptible recipients (Bondanza and others 2003; Georgiev and others 2005).

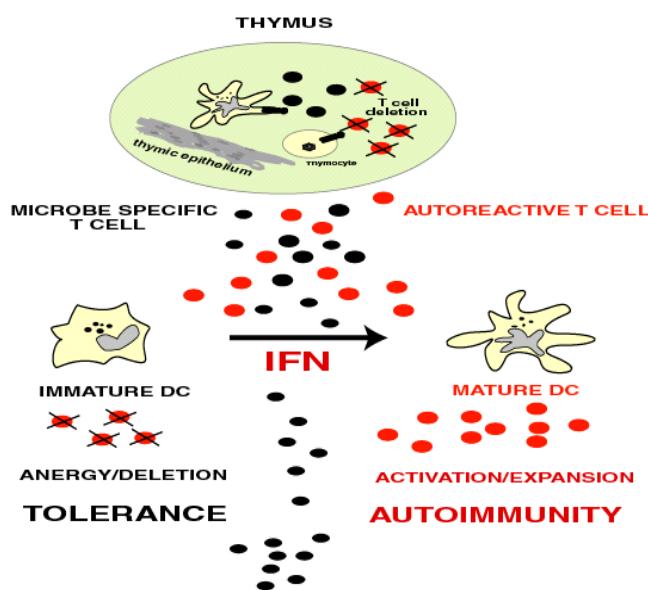

Figure 3. Fate of Autoreactive T Cells. Autoreactive thymic escapees are silenced in periphery via immature DCs, which control peripheral tolerance. Excess IFN- $\alpha\beta$  induces unabated DC maturation, which leads to activation/expansion of autoreactive T cells.

pDC numbers are reduced in SLE blood (Blanco and others 2001), but these cells massively infiltrate inflamed lupus skin (Blomberg and others 2001; Farkas and others 2001). The decrease in SLE blood pDCs might thus result from their accelerated migration to inflammation sites, as demonstrated in allergen challenged nasal mucosa (Jahnsen and others 2000). A unified view of the pathogenesis of SLE is depicted in Figure 4.

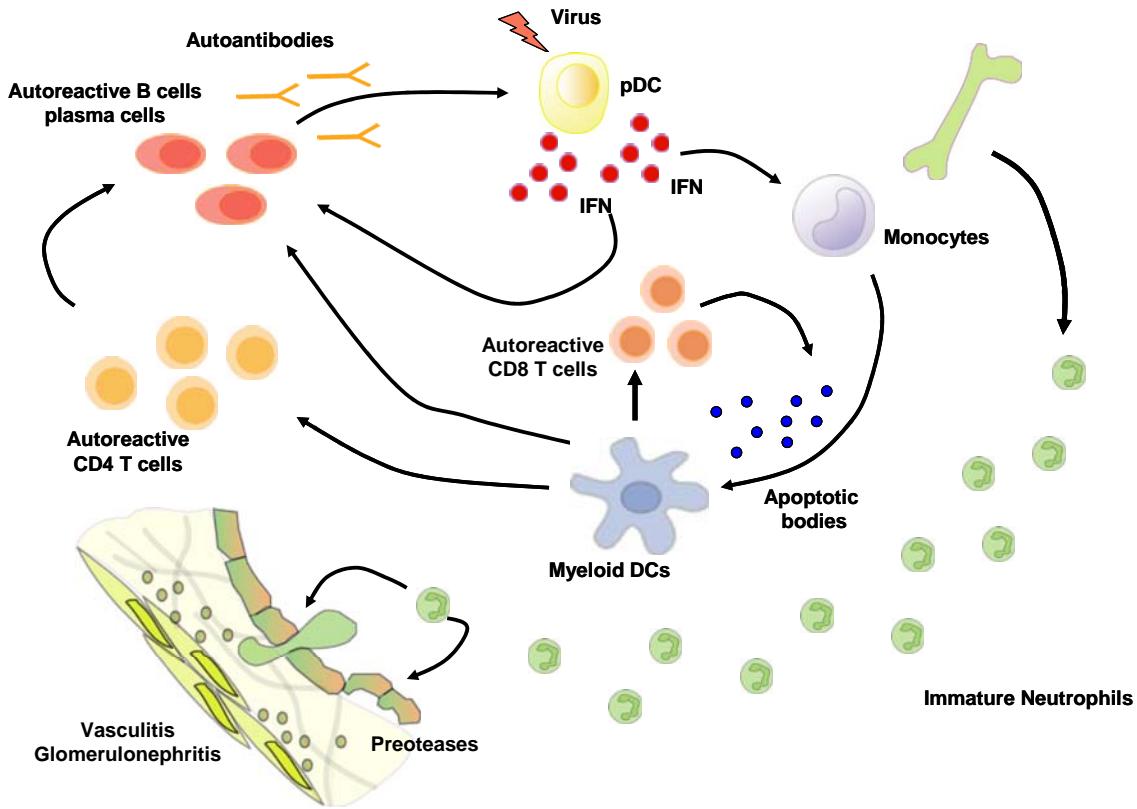

Figure 4. Increased bioavailability of IFN- $\alpha$  is fundamental to SLE pathogenesis. It induces and maintains the generation of mature DCs, tilting the fate of autoreactive T lymphocytes which have escaped central tolerance from deletion to activation. These mature DCs activate cytotoxic CD8+ T cells to generate nucleosomes which can be captured and presented by IFN-DCs. Together with IL-6, IFN promotes the differentiation of mature B cells into plasma cells. Thus, the effects of IFN- $\alpha$  on DCs, B and T cells could explain the break down of tolerance to nuclear antigens, autoantibody secretion and IC formation characteristic of SLE. Chromatin-containing IC activate i) B cells through the co-engagement of BCR and TLRs and ii) pDCs to secrete more IFN- $\alpha$  through the co-engagement of Fc $\gamma$ R and TLRs.

*Monocytes and Lupus.* Monocytes represent around 5-10 % of peripheral blood leukocytes. In both humans and mice, they originate from a myeloid precursor in the bone marrow, released in the peripheral blood and enter into tissues where they can differentiate into tissue macrophages or dendritic cells. The half life of monocytes is one day in humans and three days in mice (Tacke and Randolph 2006). In the mouse two subsets of monocytes are classified based on Gr-1 (Ly6C/G) expression, Gr-1<sup>high</sup> and Gr-1<sup>low</sup> monocytes display distinct migratory properties: (1) Gr-1<sup>high</sup>CCR2<sup>+</sup>CX3CR1<sup>low</sup>

migrate to inflamed tissue where they differentiate into dendritic cells and induce naïve T cells proliferation, and (2) GR-1<sup>low</sup>CCR2<sup>-</sup>CX3CR1<sup>high</sup> migrate to non inflamed tissues like spleen, lungs, liver, and brain (Geissmann and others 2003). Like in the mouse, two subsets of human monocytes circulate in the blood: (1) CD14<sup>+</sup>CD16<sup>-</sup>CX3CR1<sup>low</sup> and (2) CD14<sup>low</sup>CD16<sup>+</sup>CX3CR1<sup>high</sup> (Geissmann and others 2003; Passlick and others 1989; Ziegler-Heitbrock and others 1993). Monocytes migrate from the peripheral blood and differentiate into macrophages and DCs in peripheral tissues, Langerhans cells in skin, osteoclast in bone, microglial cells in CNS and Kupffer cells in liver (Gordon and Taylor 2005). In mouse, Gr-1<sup>high</sup> subsets of monocytes home to the inflamed skin and differentiate to epidermal Langerhans cells *in vivo* (Ginhoux and others 2006). In humans, CD14<sup>+</sup>CD16<sup>-</sup> monocytes differentiate into Langerhans cells in CXCL14 based *in vitro* tissue model system (Schaerli and others 2005) Some evidence suggest the presence of third subtype Gr-1<sup>int</sup> monocyte which express CCR7 and CCR8 at RNA transcription level in the mice likely to be a precursor for the lymph homing dendritic cells (Qu and others 2004) correspond to CD14<sup>+</sup>CD16<sup>+</sup> in humans (Tacke and Randolph 2006) and these subtypes believed to be precursors for Gr-1<sup>low</sup> subtype of monocytes differentiating from Gr-1<sup>high</sup> monocytes.

Alteration in the monocyte compartment of individuals with SLE have been described, since monocytes from these patients induce CD4 T cells proliferation, a characteristic of dendritic cells (Blanco and others 2001). SLE serum induces the differentiation of monocytes into dendritic cells, and this differentiation capacity of SLE serum depends on the presence of type-I IFN based on evidence that using a neutralizing anti-type-I IFN antibody abrogates the capacity of the serum to induce dendritic cell

differentiation. This effect of SLE serum was reproduced when type I IFN was reconstituted in human AB serum, but could not be reproduced using fetal calf serum (FCS) reconstituted with type-I IFN. Based on these observations, our hypothesis is that there are other serum factor(s) present in SLE serum which contribute to the differentiation of monocytes into dendritic cells. This hypothesis will be investigated in these studies using gene expression profiling as a tool. SLE monocytes will be studied to determine whether or not they harbor intrinsic defects or if the cytokine microenvironment in which these cell develop can explain their abnormal behavior.

### *What Have We Learned From the Animal Models of Lupus?*

*Overview.* Several murine lupus models exist, though none of them appears to fully reproduce the human disease. They can be divided into: (1) spontaneous, (2) congenic, and (3) engineered models (Liu and Mohan 2006).

The best known spontaneous models arise on New Zealand Black (NZB), New Zealand White (NZW), MRL, BXSB and SWR backgrounds. Hybrids of some of these background strains, like the NZB/W F1, NZM2410 and the SWR/NZB F1 develop anti-nuclear antibodies, glomerulonephritis and other features of human disease. The *lpr* (*Fas*) or *gld* (*FasL*) mutations on the MRL background give rise to mice with features of human lupus (Liu and Mohan 2006). Yet, the massive degree of lymphoproliferation that occurs in these mice is not found in humans. Additionally, although MRL-lpr/lpr mice spontaneously develop arthritis, it displays more features of rheumatoid arthritis than of the arthropathy seen in human SLE. Conversely, humans carrying mutations in the *Fas/FasL* genes do not develop SLE. The *yaa* mutation, which accelerates disease on the

BXSB background, is due to a translocation of the TLR7 gene into the Y chromosome, explaining the predominantly male predisposition to disease in this particular model (Pisitkun and others 2006; Subramanian and others 2006), which is at striking difference with the 9:1 female to male ratio in human SLE.

Congenic mice bearing individual predisposing loci on lupus-resistant strains have been generated. The best studied models bear the NZM2410-derived *Sle1*, *Sle2* and *Sle3/5* intervals on the B6 background (Liu and Wakeland 2001). These models underscore the importance of epistatic interactions among different loci. *Sle1*, for example, is a genetic interval responsible for breaking B cell tolerance to chromatin. However, this interval does not lead to disease manifestations unless in epistasis with *Sle2* (B cell hyperactivity), *Sle3/5* (APC hyperactivity), *Yaa* (TLR7 duplication) or *lpr* (Fas mutation).

Many lupus-like syndromes arise in mice deficient in single genes. They fall into two main categories: (1) clearance of apoptotic cells and (2) lymphocyte activation and survival. Genes within the first (C1q, C2, C4 and Dnase I) and second (CD45, CTLA-4, PD1 and Fc $\gamma$ RIIb) groups are also candidate susceptibility genes in humans according to linkage and/or association studies (Alarcon-Riquelme 2005).

*IFN in mouse models.* Recent studies in lupus-prone mice confirm the critical role of IFN- $\alpha\beta$  in SLE pathogenesis. *In vivo* delivery of IFN- $\alpha$  to preautoimmune NZB/W F(1), rapidly results in severe SLE. Anti-dsDNA antibodies appear as early as 10 days after initiation of IFN- $\alpha$  treatment, demonstrating a critical role for IFN- $\alpha$  in the selection and expansion of autoreactive clones. Proteinuria and glomerulonephritis-induced death occurred in all treated mice at 9 and 18 weeks respectively, a time when

untreated mice did not show any sign of disease (Mathian and others 2005). Conversely, the cross of both NZB and B6 *lpr/lpr* mice with a type-I IFN receptor KO strain significantly decreases morbidity and prolongs the survival of these animals (Braun and others 2003; Santiago-Raber and others 2003). As opposed to the NZB/W model, IFN- $\gamma$  but not IFN- $\alpha\beta$  seems to mediate disease in the MRL*lpr* mice. Indeed, deficiency of the IFN- $\gamma$  or the IFN- $\gamma$  receptor genes lead to a delay in both the onset of disease and the severity of glomerulonephritis (Balomenos and others 1998; Peng and others 1997) while these symptoms are enhanced when the mice are rendered deficient in the type-I IFN receptor (Hron and Peng 2004). These data, together with the expression of a strong IFN- $\gamma$  gene signature in the spleen (Liu and others 2006), support the role IFN- $\gamma$  in the *lpr* model.

#### *Project Objectives*

Healthy monocytes are immunologically quiescent cells. The monocyte compartment in circulating blood is heterogeneous in nature and are comprised of at least three subsets: CD14<sup>high</sup>CD16-, CD14<sup>high</sup>CD16+, and CD14<sup>low</sup>CD16+, each with different migratory properties. Among these subsets, the CD14<sup>low</sup>CD16+ monocytes may be a potential source of precursors for DC in the normal steady-state (Randolph and others 2002).

In SLE patients, however, these cells are altered. Specifically, monocytes isolated from these patients display DC function – that is, they are able to induce the proliferation of allogeneic T cells. Furthermore, sera from SLE patients can induce normal monocytes to differentiate into DCs. This DC-inducing property may be due to the presence of type-I

IFNs in SLE serum (Blanco and others 2001), as well as other, yet uncharacterized factors (Gill and others 2002).

The overall goal of this project is to study and characterize the monocyte compartment of SLE patients in an effort to identify alterations at both the genomic and proteomic level that may help explain some of these unusual features displayed by SLE monocytes. Along with this, studies have been delineated in an effort to try to identify additional uncharacterized factors in SLE sera, which may induce the differentiation of monocytes into dendritic cells.

To this end, the following specific aims will be addressed:

1. Phenotypic characterization of SLE monocytes
2. Gene Expression Profiling of SLE monocytes
3. Characterization of the effects of SLE serum on healthy monocytes

## CHAPTER TWO

### *Materials and Methods*

#### *Subjects*

##### *Patients*

All SLE patients were collected from the Pediatric Rheumatology Clinic at Texas Scottish Rite Hospital in Dallas, Texas.

A total of 51 SLE patients including 7 males and 44 females, were studied in this project. The average age of the patients at the day of sample collection was 15 years (range, 8 to 19), and the average duration of SLE was 0.69 years (range, 0 to 2.06 years). The breakdown of the patients with regards to ethnicity was as follows: 45% Hispanic, 27% African American, 18% Caucasians, 4% Asian, and 2% unspecified. Table 5 shows the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) and medications for each patient in the study.

##### *Healthy Donors*

The control population consisted of 21 randomly selected healthy children, including 5 males and 16 females, with an average age of 12 years (range, 6 to 22). The ethnic breakdown of the healthy donors was as follows: 42% Caucasian, 29% Hispanic, 19% African American, and 10% Asians.

### *Blood Collection*

Whole blood samples were collected from pediatric patients and healthy donors using standard venipuncture techniques. Blood was drawn in either EDTA or sodium citrate vacutainer tubes (BD, Franklin Lake, NJ) for the cellular immunology experiments, and the samples were utilized within four hours of collection. All blood collection protocols were reviewed and approved by the Institutional Review Board at the Baylor Research Institute, at Texas Scottish Rite Hospital in Dallas, Texas.

### *Isolation/Purification of Cell Subsets*

#### *Peripheral Blood Mononuclear Cells*

A standard protocol for lymphocyte separation with modifications was used for isolation of peripheral blood mononuclear cells (PBMCs) (Marjorie E. Kanof 2007). Briefly, after blood collection, tubes containing EDTA or sodium citrate were centrifuged at 2400 rpm for 10 minutes to separate the plasma from the cells. Plasma was then collected in separate 50ml conical tubes, and the remaining sample diluted in PBS (2X the remaining volume). Diluted blood cells were then layered onto Lymphocyte Separation Media (half the volume of diluted blood) Cellgro® (Mediatech Inc., Herndon, VA) in a separate 50 ml conical tube, and the tubes were centrifuged in a Sorvall/Heraeus MultiFuge® 3S-R centrifuge at 1800 rpm for thirty minutes at room temperature without brake. After centrifugation, cells at the interface were collected and transferred to a 50 ml tube, washed with PBS, and spun down at 1400 rpm at 4 °C. The supernatant was removed, and cells were transferred to a 15 ml tube conical tube. Finally, the cells were washed again with PBS and spun down at 1000 rpm for 10 minutes at 4 °C.

### *Monocytes*

Monocytes were isolated from PBMCs from healthy donors and SLE patients by positive selection with CD14 Micro Beads (Miltenyi Biotec, Auburn, CA) as per the manufacturer's protocol. Briefly, every  $10^7$  PBMCs were resuspended in 80ul of PBS and incubated with 20ul of CD14 Micro Beads on ice for 20 minutes. Cells were then passed through an MS column (Miltenyi Biotec, Auburn, CA) using a VarioMACS™ magnetic separator (Miltenyi Biotec, Auburn, CA). The column was washed two times with ice cold PBS. After washing, the column was removed from the magnet; and cells were collected in a 15ml conical tube with ice cold PBS using a plunger. Monocytes were washed and counted, and their purity was checked by flow cytometry using the following antibody cocktail: CD14-FITC (M5E2), CD3-PE (HIT3a), HLA-DR-PerCP (L243) and CD19-APC (SJ25C1). Samples with a purity of >97% were utilized for further processing.

### *CD4 T Cells*

PBMCs were isolated as described above and washed three times with PBS. CD4 T cells were then enriched using a StemSep™ Human CD4<sup>+</sup> T Cell Enrichment Kit (StemCell Technologies, Inc., U.S.A). Briefly, PBMCs were incubated with a CD4 T cell enrichment antibody cocktail for 20 minutes at room temperature, then incubated

further with magnetic colloid for 20 minutes, and finally passed through a CS column (Miltenyi Biotec, Auburn, CA) and washed with PBS to enrich CD4 T cells. Possible contaminating dendritic cells were removed by using anti-HLA-DR magnetic beads (Miltenyi Biotec, Auburn, CA). CD4 T cells were counted and frozen at -80 °C.

#### *Cell Sorting of Myeloid Dendritic cells (mDC) and Monocytes*

Myeloid dendritic cells and monocytes from healthy volunteers were sorted on a FACS Aria® (BD Bioscience, Franklin Lakes, NJ) as Lineage-, CD11c<sup>+</sup> HLA-DR<sup>+</sup> and CD14<sup>+</sup>HLA-DR<sup>+</sup> cells respectively.

#### *Cell Staining*

#### *Immunofluorescence*

Monocytes, either from PBMCs (purified or unpurified) or harvested from cell culture experiments were stained with various conjugated antibodies (Table 8) using staining buffer (PBS+2% FCS) and Fc blockers (Miltenyi Biotec, Auburn, CA). Cells were washed after staining, fixed in 2% paraformaldehyde solution, and stored at 2-8°C prior to data acquisition. For whole blood staining, blood was incubated with antibodies and cells were lysed with BD FACS™ Lysing Solution (BD Biosciences, Franklin Lakes, NJ), washed, and fixed in 2% paraformaldehyde. Sample data was acquired on a BD FACSCalibur™ System (BD Biosciences, Franklin Lakes, NJ), analyzed using either CellQuest™ Pro (BD Biosciences, Franklin Lakes, NJ) or FlowJo (Tree Star, Ashland, OR) analysis software, and stored on a local BIIR server.

### *CFSE Staining*

Frozen CD4 T cells were thawed, washed, and live cells were counted. Ten million CD4 T cells were resuspended in 1ml of PBS (Invitrogen Corporation, Carlsbad, CA) and stained with 1uM Carboxy Fluorescein Succinimidyl Ester (CFSE) (Invitrogen Corporation, Carlsbad, CA) for ten minutes in the dark. Staining was blocked with cold complete RPMI medium containing ten percent human AB serum. Cells were washed twice, resuspended in complete RPMI containing human AB serum and counted for viability.

## *In Vitro Experiments*

### *Effect of IFNa2b on Monocytes*

Blood monocytes isolated from healthy volunteers were incubated with 20% autologous serum alone or in the presence of 1000U/ml of IFNa2b (Schering Plough, Kenilworth, NJ) in 6-well plates at a concentration of  $10^6$  monocytes per well in 3 ml of media. After incubating for one hour at  $37^{\circ}\text{C}$ , cells were harvested and RNA was extracted. Identical experiments were done after the following incubation time points: six hours, twenty four hours, two days, and three days.

### *Effect of Lupus Sera on Monocytes*

Blood monocytes isolated from healthy volunteers were incubated in RPMI supplemented with L-glutamine, Gentamicin, and Penicillin in 6-well plates (1,000,000 cells/well/3 ml of medium) with either 20% autologous serum or 20% SLE sera from active and untreated lupus patients. Cells were harvested and RNA was extracted after a 6 hours incubation. In the same experimental setting, type-I IFNs were blocked in SLE serum by antibodies against human IFN- $\alpha$  (15000 neutralizing units), human IFN- $\beta$  (3000 neutralizing units), and human IFN $\alpha/\beta$  receptor chain 2 (3.5 ug) (PBL InterferonSource, Piscataway, NJ). Soluble IFNs in SLE were sera blocked with anti IFN- $\alpha$  and anti IFN- $\beta$  and monocytes were blocked with anti receptor antibodies for 30 minutes at  $37^{\circ}\text{C}$  prior to mixing both in culture plate.

In some experiments, blood monocytes isolated from healthy volunteers were incubated in RPMI supplemented with L-glutamine, Gentamicin, and Penicillin in 24-

well plates (500,000 cells/well/1 ml of medium) with either 20% autologous serum or 20% SLE sera from active and untreated lupus patients.

#### *Migration Assay*

Healthy monocytes were incubated with 20% autologous sera or SLE sera for 16 hours. Cells were then harvested and an *in vitro* transwell migration assay was performed. Briefly, a 5 um-pore size insert with a polycarbonate membrane designed for a 24 well-plate was used for this assay (Corning Incorporated, Corning, NY). The lower chamber contained 600 ul of 0.5ug/ml of CCL19 solution in RPMI supplemented with L-glutamine, Gentamicin, and Penicillin. A total of  $0.5 \times 10^6$  monocytes in 200 ul of the same media were added to the upper chamber. The plate was incubated at 37 °C for 3 hours, and the number of migrated cells was counted by flowcytometry using CountBright™ Absolute Counting Beads (Invitrogen Corporation, Carlsbad, CA).

#### *Mixed Lymphocyte Reaction*

CFSE labeled CD4 T cells ( $1 \times 10^5$ ) were incubated with monocytes ( $2 \times 10^4$ ) in 96-well plates in complete RPMI medium. Cells were harvested at six hours, 2 days, and 5 days. After 6 hours of culture, harvested cells were enriched by depleting T cells with CD3 Dynabeads® (Invitrogen, Carlsbad, CA), and RNA was extracted for use in microarray testing. After two days of culture, cells were harvested, and monocytes were stained for different cell surface markers. After five days of culture, cells were harvested, and the CFSE dilution was measured to assess the level of T cell proliferation.

## *Microarray Testing and Analysis*

### *RNA Extraction and Quantitation*

RNA was extracted using either the RNeasy® Mini Kit (Qiagen, Valencia, CA), if  $> 5 \times 10^5$  were recovered, or PicoPure™ RNA Isolation Kit (Molecular Devices Corporation, Sunnyvale, CA) when  $< 5 \times 10^5$  cells were recovered. The quantity of the RNA was determined by NanoDrop® ND-1000 UV-Vis Spectrophotometer (NanoDrop Technologies Wilmington, DE) by measuring 1 ul of the RNA solution against water as a blank. RNA integrity was determined using the Agilent 2100 bioanalyzer (Agilent Technologies, Santa Clara, CA) in which the RNA integration number (RIN) is expressed as a quality factor. Only RNA samples with a RIN of  $> 7.0$  were used for final hybridization in the microarray assay.

### *Labeling and Hybridization of RNA Samples*

RNA was labeled using the GeneChip® Two-Cycle Target Labeling kit (Affymetrix, Santa Clara, CA) following the manufacturer's recommended procedures. cRNA was fragmented and hybridized to the HG-U133A & HG-U133B Affymetrix GeneChip® arrays that contain 45,000 probe sets at 45°C for 16 hours. GeneChip arrays were washed, stained, and scanned according to protocols described in the GeneChip Expression Analysis Technical Manual (Affymetrix, Santa Clara, CA). Scanned GenesChips were inspected visually for abnormalities or irregularities.

### *Microarray Data Analysis*

For each Affymetrix U133A and B GeneChip®, raw intensity data were normalized to the mean intensity of all measurements on that array and scaled to a target

intensity value of 500 (TGT), using Affymetrix Microarray Suite 5.0 software. Data were then further analyzed using GeneSpring software version 7.3.

To analyze the data from monocytes from untreated and treated SLE patients, 5 samples in each data set were used for final analysis, and compared to 5 samples from healthy donors. Data were normalized to this set of healthy controls. For each set of experiments, unsupervised clustering of samples was performed using the list of genes present in at least one sample to rule out technical variability. For supervised analysis, an Affymetrix flag call of ‘present’ in 3 out of 5 samples from each cohort was used to designate the filter for a reliable intensity measurement from each individual gene chip. These two lists combined were used as a quality control measure for class comparison, which was performed using a non-parametric ranking statistical analysis test (Mann Whitney) as well as a 2-fold difference in the average normalized value of healthy to test set. Genes from both class comparison methods were combined, and noise in the final data was reduced by filtering genes with a raw value of >200 in 3 out of 5 test samples, compared to the average raw signal from the healthy control set.

In the alloreaction experiments, data was normalized to monocytes that did not induce an alloreaction. An Affymetrix flag call of ‘present’ in 3 out of 4 samples of each cohort was used to designate the filter for a reliable intensity measurement from each individual gene chip. These two lists combined were used as a quality control measure for class comparison, since there was a 2-fold difference in the average normalized value of the two groups of monocytes. Possible noise in the final data was reduced by filtering in genes with expression raw values of >200 in 3 out of 4 monocyte samples inducing

alloreaction compared to the average raw value of monocytes which did not induce an alloreaction.

To identify monocyte genes up- or down-regulated after incubation with SLE serum, data were normalized to data from the corresponding control experiment using autologous serum. An Affymetrix flag call of ‘present’ in 3 out of 3 samples and a raw value of  $> 200$  for each condition was used to designate the filter for a reliable intensity measurement from each individual gene chip. These two lists combined were used as a quality control measure for class comparison, since there were 2 fold differences in the average normalized values from the two groups of experiments.

In order to determine the global pattern of IFN-regulated genes in untreated SLE monocytes compared to healthy controls, a K-mean clustering algorithm was applied to genes expressed in untreated SLE monocytes cultured with IFN and harvested at different time points (1hr, 6hrs, 24 hrs, 2 days and 3 days).

## CHAPTER THREE

### *Results*

#### *Phenotypic Characterization of SLE Monocytes*

The differential expression of CD14 and CD16 (also known as Fc $\gamma$ RIII) defines two major subsets of monocytes in peripheral blood: the “classical” CD14 $^+$ CD16 $^-$  monocytes, typically representing up to 95% of the monocytes in healthy individuals, and the “non-classical” CD14 $^{low}$ CD16 $^+$  monocytes comprising the remaining fraction of monocytes (Passlick and others 1989; Ziegler-Heitbrock and others 1993). These subsets differ in many respects, including adhesion molecule and chemokine receptor (CCR) expression. CD14 $^+$ CD16 $^-$  monocytes express CCR2, CD62L (L-Selectin) and FC $\gamma$ RI (CD64), whereas CD14 $^{low}$ CD16 $^+$  monocytes lack CCR2, and have higher levels of MHC-II and FC $\gamma$ RII (CD32) (Ancuta and others 2003; Geissmann and others 2003; Gordon and Taylor 2005; Weber and others 2000; Ziegler-Heitbrock and others 1993). Considerable heterogeneity exists however in the minor CD16 $^+$  monocyte fraction. An “intermediate” population of monocytes that is CD14 $^+$  (as opposed to CD14 $^{low}$ ) and CD16 $^+$  differentiates in vitro differently than CD14 $^{low}$ CD16 $^+$  monocytes (Grage-Griebenow and others 2001a). CD16 $^+$  monocytes have been described to differentiate into antigen-presenting DCs (Grage-Griebenow and others 2001a; Randolph and others 2002). The extent to which human monocyte subsets differentiate into DCs *in vivo* is however too complex to predict, as both the phenotype of the cultured monocytes and factors present in the *in vitro* culture are expected to have a strong influence on the differentiation.

Previous work at our Institute revealed that blood monocytes from a fraction of pediatric SLE patients function as DCs (Blanco and others 2001). Thus, we used flow cytometry to characterize 1) the monocyte subpopulation distribution in pediatric SLE patients and healthy children, 2) the expression of molecules that might explain the acquisition of DC function by SLE monocytes. Whole blood samples were obtained after informed consent from 23 pediatric SLE patients (average age: 16.0 years) and 15 healthy children (average age: 12.2 years). The two groups were matched for gender and ethnicity. Samples (100 µl) were stained with the antibody combinations depicted in Table 5. While two major monocyte populations have been described based on expression of CD14 and CD16 in healthy adult donors, healthy children and pediatric SLE patients displayed a more complex pattern of surface monocyte staining. Indeed, 4 discrete populations could be recognized in the majority of blood samples: 1) CD14++ CD16- CD64+ CD62L+ HLA-DR<sup>low</sup>, 2) CD14++ CD16+ CD64+ CD62L+ HLA-DR<sup>high</sup>, 3) CD14+ CD16+ CD64- CD62L- HLA-DR<sup>high</sup> and 4) CD14+ CD16- CD64- CD62L- HLA-DR<sup>low</sup>. Furthermore, in a small number of healthy donors (N=3), a fifth population characterized by CD14+++ CD16- surface expression could be identified (Figure 5). According to this phenotypic scheme, pediatric SLE patients displayed an expansion of CD14++CD16+ cells ( $p=0.01$ ) while the distribution of the remaining populations did not differ from controls (Figure 6). We next analyzed monocyte surface marker expression in the same two groups of healthy and pediatric SLE patients using mAbs as described in the methods section. To our surprise, most of the molecules that are upregulated as monocytes differentiate into DCs were similarly expressed in cells from healthy children

and SLE patients (Table 5). The two main exceptions included a mild upregulation of CCR7 and a significant down-regulation of HLA-DR molecules especially within the

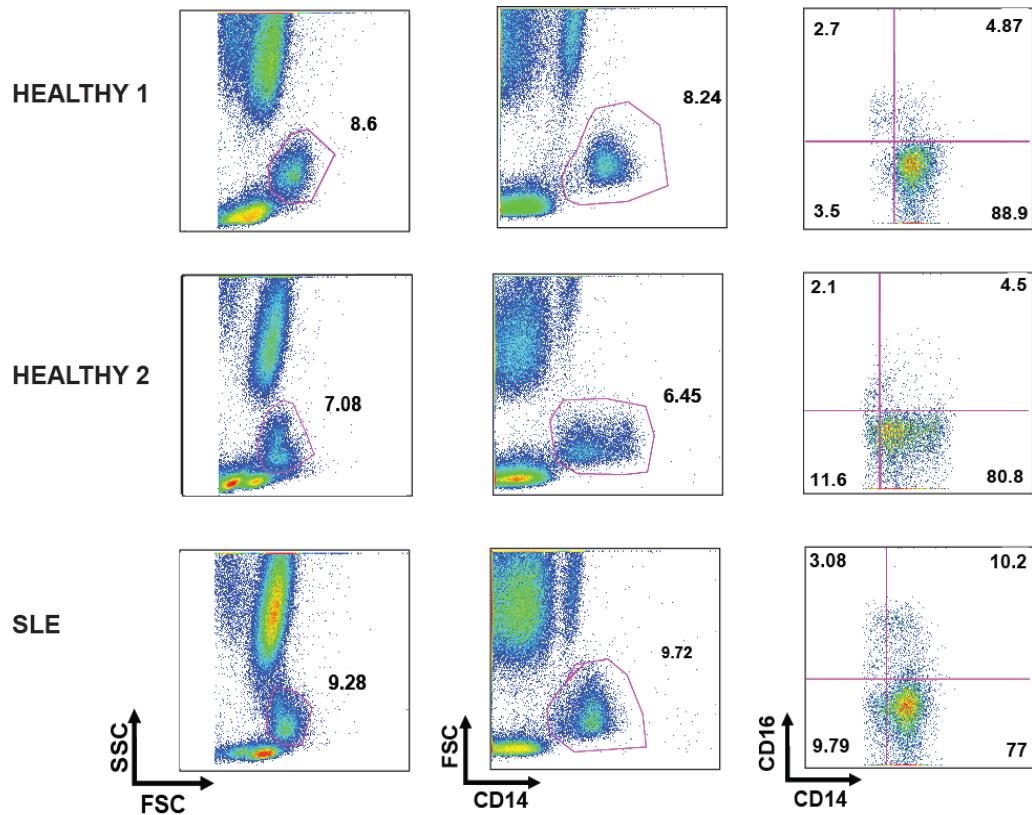

Figure 5. Distribution of major blood cells and monocyte subpopulations in two healthy children (H1 and H2) and one pediatric SLE patient. Cells were analyzed according to side and forward scatter (left panel), gated according to FSC and CD14 expression (middle panel) and further analyzed according to CD14 and CD16 expression into 4 subpopulations. Note the variability in CD14 expression among the two healthy controls.

CD14<sup>+</sup> CD16<sup>-</sup> monocyte fraction from SLE patients (Table 5 and Figure 7). CD64 and CD62L, which are normally expressed within the CD14<sup>++</sup> fraction, were mildly upregulated in SLE patients. Finally, CD81, a co-receptor for HCV and HIV which is known to be downregulated upon IFN-alpha exposure (Kronenberger and others 2001), was significantly downregulated in SLE CD14<sup>++</sup> CD16<sup>-</sup> monocytes.

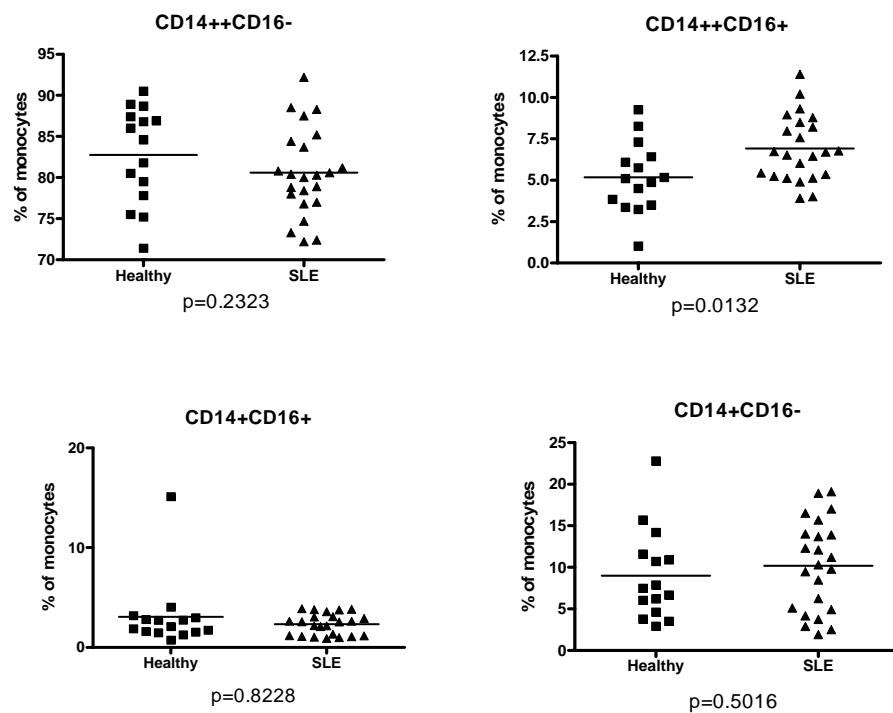

Figure 6. Distribution of major monocyte subpopulations in the blood of healthy children (N. 15) and pediatric SLE patients (N.23). P value was obtained according to non-parametric t-test (Mann-Whitney).

The fact that except for a mild upregulation of CCR7 none of the surface molecules involved in antigen presentation (i.e. HLA-DR, CD80, CD86) or in monocyte differentiation into DC (i.e. CD83) were upregulated in SLE blood monocytes led us to adopt a broader approach to identify possible differences between healthy children and patient cells.

Table 5. Subsets of monocytes (p-values between healthy and SLE)  
 \* Low in SLE blood \*\* High in SLE blood

#### *Gene Expression Profiling of SLE Monocytes*

##### *SLE Monocytes Display a Unique Gene Expression Profile*

To assess the transcriptional program of SLE monocytes, we purified these cells from the blood of 5 healthy controls and 5 pediatric SLE patients. Previous gene profiling studies in our laboratory using PBMCs from SLE patients revealed that their transcriptional program changed considerably upon exposure to the drugs used to control disease manifestations (data not shown). We therefore selected for this study blood samples from 5 active, newly diagnosed patients who had never received oral or IV medications. After CD14+ selection, the purity of the obtained monocyte fraction was >97%. RNA was extracted as described in the material & methods section and hybridized to human genome U-133 A & B chips using the Affymetrix ® platform (Figure 8). An unsupervised clustering algorithm was performed on genes present in at

least 20% of all samples. As shown in Figure 8b, monocytes from healthy donors and SLE patients clustered into two well defined groups, thus ruling out variability due to sample processing. To find genes differentially regulated in SLE monocytes, the microarray data from SLE patients was normalized to that of healthy controls (Figure 8c). This analysis yielded 1,629 transcripts as differentially regulated in SLE monocytes (Figure 8d).

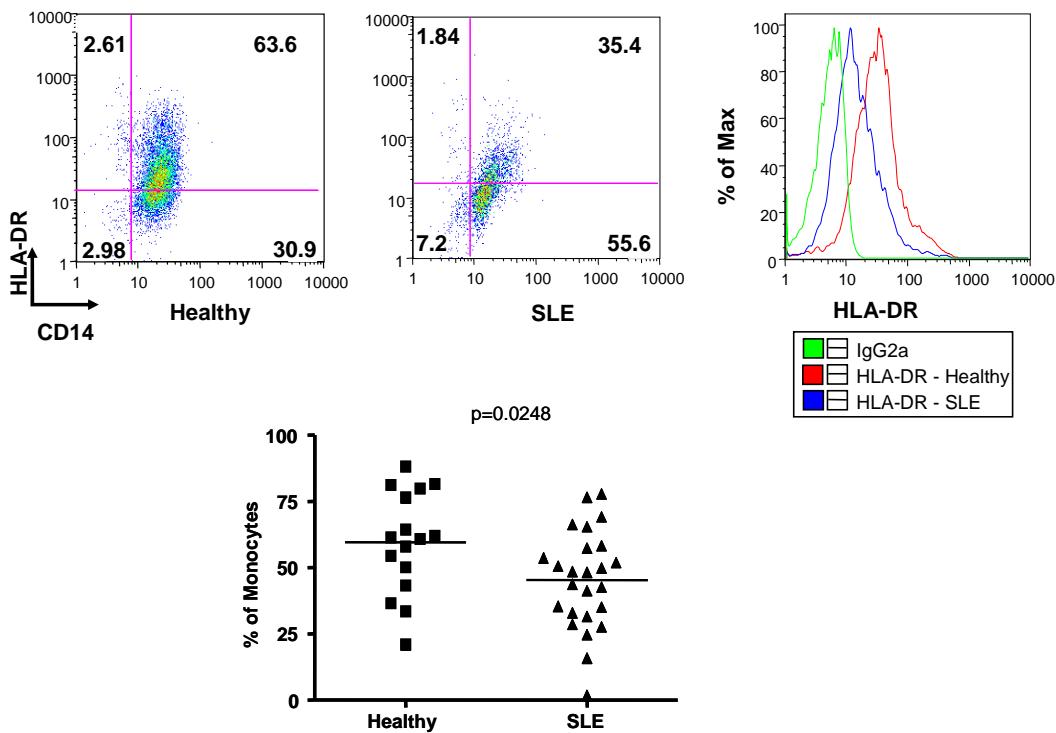

Figure 7. Downregulation of MHC class II expression on ex-vivo SLE monocytes (healthy children, n = 15; pediatric SLE patients, n = 23). p value was obtained using a non-parametric t-test (Mann-Whitney).

It has been previously shown that the presence of type I IFN in SLE serum is fundamental for the differentiation of monocytes into dendritic cells (Blanco and others 2001). Furthermore, PBMCs from >90% SLE patients express a type I IFN signature (Bennett and others 2003). We therefore surmised that a large proportion of the genes found differentially expressed in SLE monocytes might be IFN-regulated. To identify these genes, we first exposed monocytes from 2 healthy donors to type I IFN (1,000 IU of

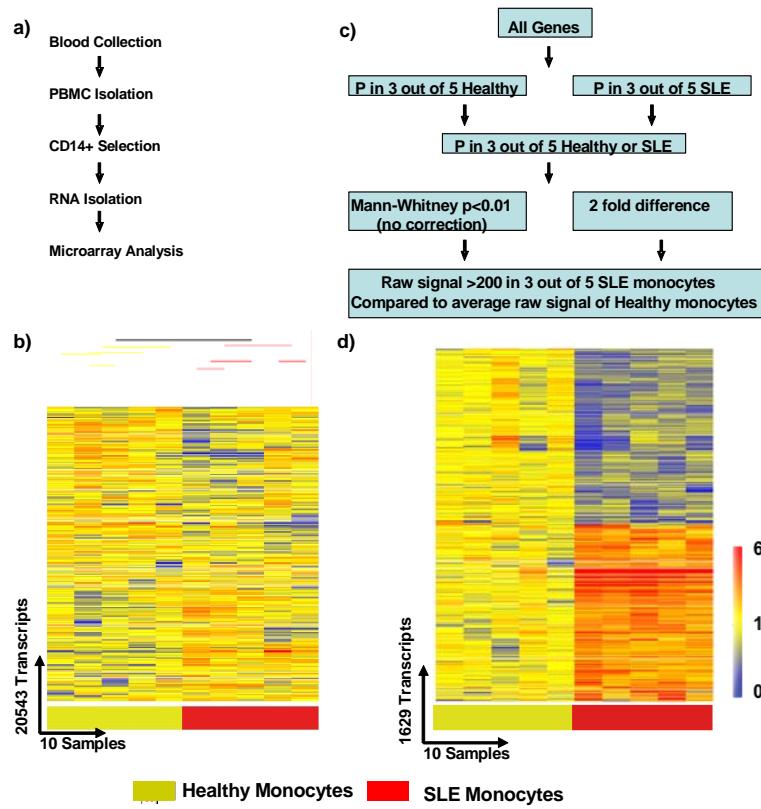

Figure 8. Differentially regulated genes in circulating monocytes of SLE patients (a) Overview of experimental design (b) Unsupervised analysis of monocytes from 5 healthy children and 5 pediatric SLE patients (transcripts present in 20% of samples) (c) Overview of supervised analysis used to find differentially regulated genes in SLE monocytes (d) Heat map of 1629 transcripts expressed in SLE monocytes (each column represents an individual sample)

recombinant IFN- $\alpha$ 2) in vitro. RNA was extracted at different incubation time points (1, 6, 24, 48 and 72 hr) and processed for microarray analysis as described in materials and methods.

We found that >35% (606/1629) of the transcripts dysregulated in SLE monocytes were *bona fide* type I IFN induced. Figure 9b shows the gene trees of type I IFN regulated genes in *ex vivo* SLE monocytes as well as in healthy monocytes exposed *in vitro* to type I IFN at different time points. This kinetic analysis allowed us to conclude that the bulk of *in vitro* IFN-induced transcriptional changes is observed at 6 hr and is maintained for up to the 72 hr time point. A group of transcripts ( $N=226$ ) was already dysregulated however 1 hr after exposure to IFN-alpha. Very few transcripts ( $N=21$ ) appeared to be the result of late (24 hr or later) IFN induction (Supplementary Figure

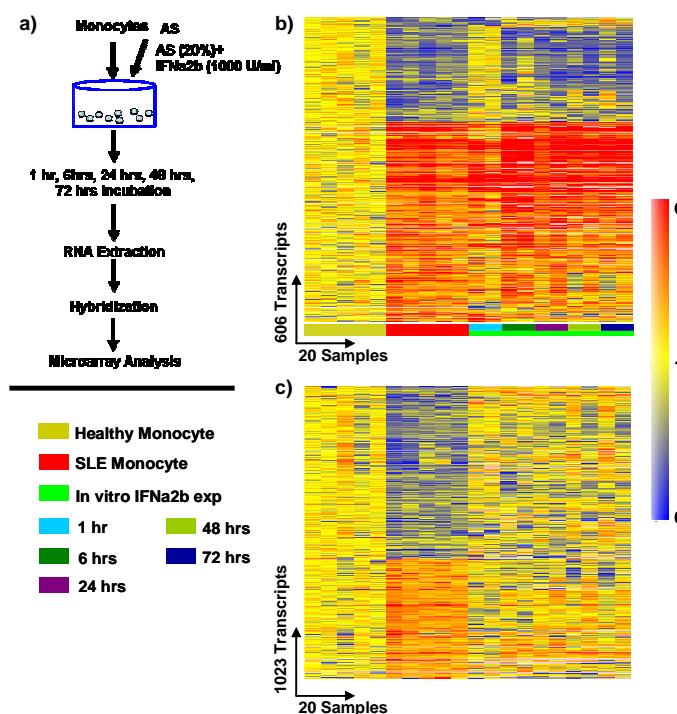

Figure 9. Kinetic study of IFN-inducible genes expressed in circulating blood monocytes from SLE patients. (a) Overview of experimental design (b) IFN- inducible genes regulated in SLE monocytes (c) 1023 transcripts expressed in SLE monocytes that are not type I IFN regulated.

1). The remaining 1023 transcripts were not considered to be type I IFN regulated as either they were not up or down-regulated in culture at any time point during the 72hr of exposure to IFN-alpha (Figure 9c), or their fold expression changed but their raw expression value in vitro did not reach the value that we selected as threshold to document true changes in expression. This, therefore, might represent a significant underestimation of the effects of IFN-alpha. Indeed, many factors, such as the survival of monocytes in culture, may affect the transcriptional activity of these cells. Only an *in vivo* experiment (i.e. administration of IFN alpha to a healthy volunteer and subsequent longitudinal follow up) would allow us to fully address this question.

Within the 606 transcripts that we selected as *bona fide* type I IFN-regulated, we found dysregulation of most of the genes that previous work with PBMCs from SLE patients in our laboratory had identified as components of the IFN-signature in (i.e. IFI27, IFIT1-3, IFI44, IFI44L, MX1 and OAS) (Bennett and others 2003). Other significantly upregulated genes encoded apoptosis-inducing molecules such as TRAIL and FAS; adhesion molecules such as sialoadhesin, a monocyte/macrophage specific lectin, SLAMFM7 (CRACC), a member of the CD2 family of cell surface receptors implicated in the activation of NK cell-mediated cytotoxicity, ITGB7, a receptor for fibronectin, MADCAM1 and VCAM1, and claudin 23, a molecule that plays a major role in tight junction-specific obliteration of the intercellular space; ubiquitination such as culin 1, an essential component of the SCF (SKP1-CUL1-F-box protein) E3 ubiquitin ligase complex, which mediates the ubiquitination of proteins involved in cell cycle progression, signal transduction and transcription and, ISG15 and its deconjugating protease USP18; chemokines and chemokine receptors such as CXCL10 (IP10), CCR1,

CCR5, CCL2 (MCP1) and CCL8 (MCP2); and Fc receptors such as CD64 (Fc $\gamma$ RIA), which is normally expressed on CD14<sup>high</sup> monocytes.

Within the list of genes that we could not formally ascribe as IFN alpha-regulated (in part due to the limitations of the in vitro experiments), there was a remarkable down-regulation of ribosomal protein- and HLA class II-encoding transcripts. Thus, gene expression profiling of ex vivo SLE monocytes did not provide a clear-cut answer to the question of what made these cells function as DCs. Figure 10 depicts genes involved in IFN signaling pathway (a), antigen presentation (b), as well as molecules characteristically expressed by the CD14<sup>high</sup>CD16<sup>+</sup> subsets of monocytes.

## *There is Little Transcriptional Overlap between SLE Blood Monocytes and Healthy Blood mDC*

To find genes which could explain the DC characteristics of SLE monocytes, blood mDCs were sorted from five healthy individuals as Lineage<sup>-</sup> HLA-DR<sup>high</sup> CD11C<sup>high</sup> cells and their transcriptional programs were compared to those of blood CD14+ monocytes isolated from the same donors (figure 11). An unsupervised clustering analysis performed on genes present in 20% of the samples (19,216 transcripts), and that included SLE blood monocytes, showed that the observed changes were not due to technical variability, as healthy blood monocytes, SLE blood monocytes and healthy blood mDC clustered into well defined groups (Figure 12b). A supervised analysis was then performed to find 1) genes differentially expressed in healthy blood mDCs compared to healthy monocytes, 2) similarly expressed in healthy blood mDCs and SLE blood monocytes.

**Lineage - CD11c+ mDC and CD14+ monocytes were sorted from the blood of 5 healthy donors**

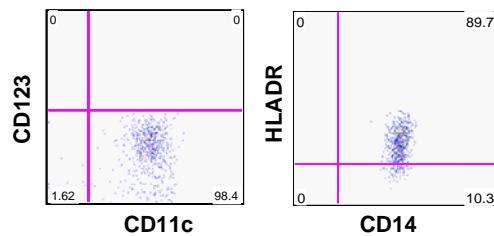

Figure 11. Flow cytometric representation of purity of blood circulating dendritic cells and monocytes sorted from healthy donors (N=5). Blood mDC and monocytes sorted based on their expression of Lineage-CD11c+ and CD14+, respectively.

Healthy blood mDCs differentially express 2,408 transcripts compared to monocytes. Among them, and as expected, HLA class II genes were significantly upregulated and CD14 was downregulated. None of the known co-stimulatory molecules

that become upregulated during DC maturation (i.e. CD80, CD86 etc.) were differentially expressed at the transcriptional level however in healthy blood mDCs. Among Toll-like receptors (TLRs), TLR2, 4, 5 and 8 were significantly down-regulated while TLR-3 and 10 were upregulated.

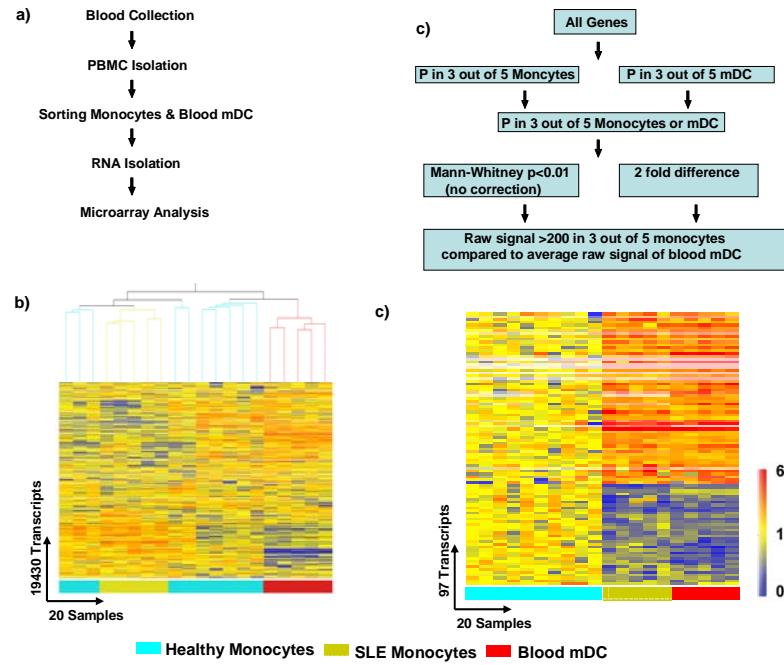

Figure 12. SLE blood monocytes and healthy blood mDC show little transcriptional overlap. a) Overview of experimental design; (b) Unsupervised analysis comparing monocytes from healthy donors ( $n=10$ ), monocytes from SLE patients ( $N=5$ ), and blood mDC from healthy donors ( $N=5$ ); (c) Only 97 of the 2408 mDC transcripts are expressed in SLE monocytes which include genes involved in adhesion, chemotaxis, innate immunity, signal transduction, and transcription.

To our surprise, only 97 of the 2,408 “mDC transcripts” were similarly expressed in blood SLE monocytes. Among these, the most significant similarities were found in genes involved in 1) adhesion (i.e. ITGB7, SLAMF7 and AMIGO2), 2) chemotaxis (i.e. FPR1L2 and CCR5), 3) cytoskeleton (AKAP2), 4) innate immunity (TLR5), 5) signal transduction (CD2AP and GPR18), and 6) transcription (ETS1, ARID5B, HOXA9). As none of the proteins encoded by these genes could easily explain the DC function of SLE

monocytes, we decided to explore the possibility that contact with T cells might be required in order for SLE monocytes to acquire an antigen-presenting transcriptional program and/or phenotype.

*Upon Exposure to Naïve CD4+ T Cells, Blood Monocytes from Some SLE Patients Acquire DC Properties*

As previously published (Blanco and others 2001), not every SLE patient displays blood monocytes able to induce alloreactive CD4+ T cell proliferation. Thus, we screened SLE monocytes from SLE patients (N=19) in standard alloreactions and, as described in Figure 13, we classified samples based on either capacity to induce CD4 T cell proliferation or not. CFSE labeled CD4 T cells ( $10^5$ ) were incubated with monocytes ( $2 \times 10^4$ ). Cells were harvested at 6 hours, 2 days, and 5 days. After 6 hours of culture, the monocytes were enriched by depletion of CD3+ T cells, and their RNA was prepared for microarray analysis. After two days of culture, cells were harvested and monocytes were stained for different cell surface markers. After five days of culture, cells were harvested and CFSE concentration was measured to assess the level of T cell proliferation (Figure 13).

Unsupervised clustering performed on genes present in 20% of the samples (18,022 transcripts) classified samples into two distinct groups which correlated with their capacity to induce CD4 T cell proliferation (Figure 13b). Supervised analysis to find differentially regulated genes (between SLE monocytes which induced MLR and those which did not) disclosed 265 transcripts differentially regulated in these two groups (Figure 13c).

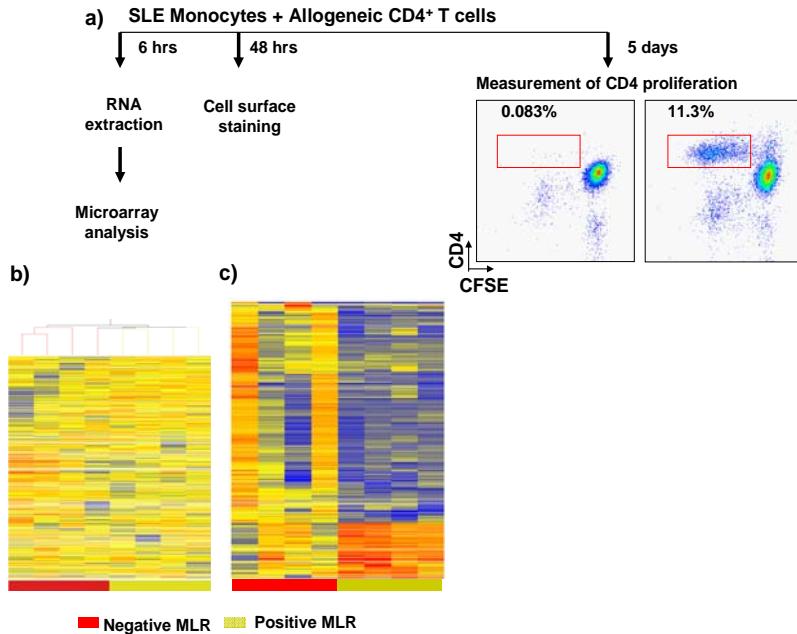

Figure 13. Gene expression profile in SLE monocytes after exposure to naïve CD4 T cells. (a) Experiment design for mixed lymphocyte reaction of SLE monocytes and allogeneic CD4 T cells. Microarray assay was performed on SLE monocytes after 6 hours of culture with CD4 T cells. Cell surface staining was done after 48 hours of culture. At day 5, CD4 T cell proliferation was measured by CFSE dilution. (b) Unsupervised clustering of genes present in 20% of samples (n=8 samples). This analysis separates SLE monocytes that induce CD4 T cells proliferation from those that do not. (c) SLE monocytes that induce T cell proliferation express 265 transcripts different from those monocytes that do not induce T cell proliferation.

All SLE monocyte samples which induced CD4<sup>+</sup> T cell proliferation upregulated MHC class II transcripts after 6 hr of culture with T cells at similar levels as blood mDC (Figure 14). On the contrary, only ¼ samples do not induce alloreactions upregulated, and to a lesser extent, HLA class II genes. Other MLR+ monocyte upregulated transcripts encoded innate immunity molecules such as IL-1 $\beta$ , KCNJ15, a potassium rectifier channel which follows the transcription pattern of IL-1 $\beta$ , MARCO, a receptor involved in actin cytoskeleton rearrangements and down-regulation of antigen uptake function during DC maturation (Granucci and others 2003), and CXCL10, a ligand for CXCR3 that is induced by type I and type II IFN and may play a key role in IFN- $\gamma$  mediated responses (Figure 14).

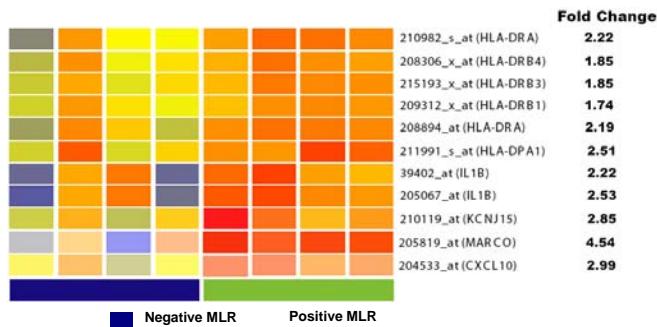

Figure 14. SLE monocytes that induce CD4 T cell proliferation upregulate MHC class II molecules. The level of expression is similar to blood circulating mDCs. These SLE monocytes samples also overexpress transcripts encoded innate immunity molecules such as IL-1b; KCNJ15, a potassium rectifier channel which follows the transcription pattern of IL-1b; MARCO, a receptor involved in actin cytoskeleton rearrangements and down-regulation of antigen uptake function during DC maturation; and CXCL10, a ligand for CXCR3.

This microarray data was further confirmed at two levels: first, cell surface staining of SLE monocytes after 48-hours in culture with CD4 T cells showed that the expression level of class II molecules correlated with the capacity of these cells to induce CD4+ T cell proliferation (Figure 15); second, we quantified the cytokines in the supernatant of the 5 day monocyte-T cell cultures and found increased levels of IL-1b in 3 out of 4 cultures inducing CD4 T cell proliferation (Figure 16). IL-6, which may be induced by IL-1b (Yamaji and others 2008), was elevated in the same cultures. Levels of

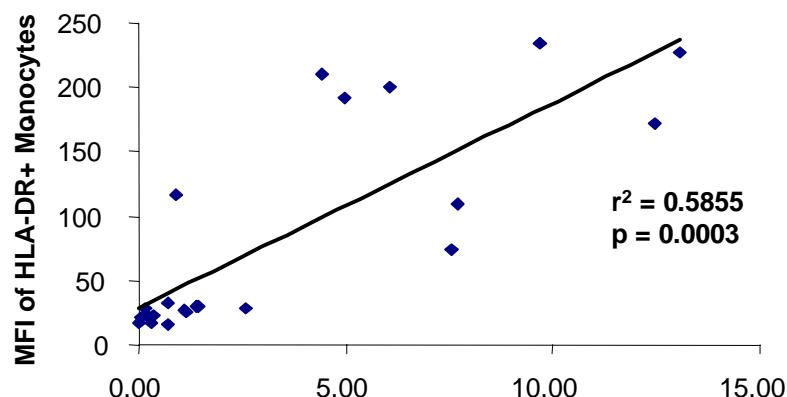

Figure 15. Expression level of HLA-DR molecules on SLE monocyte samples after contact with CD4 T cell for 48 hours. HLA-DR expression levels correlate with their capacity to induce CD4 T cells proliferation

IP-10 were elevated in  $\frac{3}{4}$  MLR + cultures, but they did not reach statistical significance when compared with those that did not induce T cell proliferation.

Thus, these studies suggest that blood SLE monocytes require signals derived from T cells in order to acquire DC function. Additionally, they point towards an important role for innate immunity receptors and/or cytokines, i.e. MARCO and IL-1b, in conferring antigen-presenting capacity to monocytes from SLE patients. How the type I IFN-rich environment of SLE blood predisposes monocytes to respond to T cell signals and/or to produce the type of cytokines that we describe above remain to be elucidated.

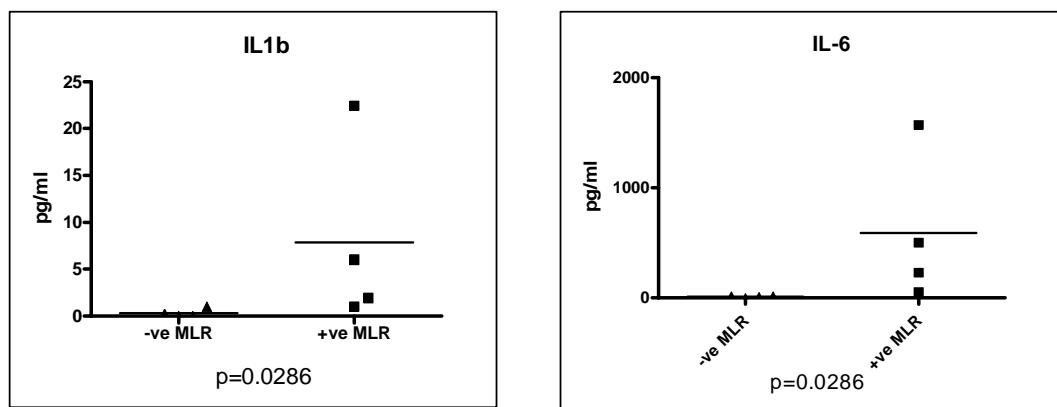

Figure 16. In 3 out of 4 cultures inducing CD4 T cell proliferation, there was an increased level of IL-1b in the culture supernatant, along with elevated levels of IL-6.

#### *Characterization of the Effects of SLE Serum on Healthy Monocytes*

An important observation from earlier work at our Institute was that the addition of SLE serum to healthy monocytes induced the differentiation of these cells into DCs (Blanco and others 2001). This effect could be reproduced by adding IFN- $\alpha$  to healthy human serum, but not to FCS. Thus, one or several components of human serum seem to be necessary to facilitate the DC-poietin activity of type I IFN. We surmised that studying the transcriptional program induced by SLE serum on healthy monocytes we might gain insight on these putative serum factor(s). This approach might also help us

recapitulate the events responsible for the skewing of monocytes into DCs during the initial stages of SLE.

*Serum from Active, Untreated SLE Patients Induces a Transcriptional profile That Includes IFN and Non-IFN Related Signatures*

Healthy monocytes were cultured for 6 hrs *in vitro* in the presence of 20% autologous serum or serum from three newly diagnosed, untreated SLE patients as described in Figure 17. Two of the three sera corresponded to patients we had also profiled their ex-vivo blood monocytes. Microarray analysis was then performed as described in materials and methods. Normalization to gene expression data from samples incubated with autologous serum yielded 2,968 transcripts differentially regulated by SLE serum. Functional characterization of these transcripts revealed a significant upregulation by SLE serum of genes involved in 1) apoptosis (TRADD, Fas, TRAIL, DR6, BIRC6, BNIPL3, etc.), 2) adhesion (JUP, CD47, SLAMF7, L-selectin, Sialoadhesin etc.), 3) cell cycle and proliferation, 4) chemotaxis (CXCL10, CXCR4, CCR7, FPRL2 etc.), 5) immune function (NOD2, TLR7, TLR8, IL6, IL15, IL4R, IFNgR2, BLyS/BAFF, FcgRIa, FcgRIIIa etc) metabolism, 6) chromatin modification and nucleosome assembly, 7) RNA processing/modification, 8) signal transduction and transcription (STAT1, STAT2, JAK2, IRAK3, SOCS3, IRF5, IRF7, ID2, RUNX3 etc), 9) translation, 10) protein modification/folding, 11) transport (TAP1, TAP2, Tapasin etc.), 12) ubiquitination etc. Many genes within each functional group were found downregulated as well. RNA-processing and protein translation-encoding transcripts were among the most abundant in this category. Figure 18 shows some of these genes,

which are involved in various pathways, such as type-I IFN signaling, antigen presentation, apoptosis, extravasation and migration.

To our surprise, only 238 of the 2,968 SLE serum-induced transcripts (~8%) overlapped with the 1,629 transcripts found dysregulated in ex-vivo SLE blood monocytes. To determine which genes could be attributed to the effect of type I IFN, we 1) compared the SLE serum-induced transcripts with those resulting from in vitro exposure of healthy monocytes to IFN-alpha for 6 hours; 2) performed blocking experiments by pre-incubating SLE sera from the 3 patients with antibodies against IFN  $\alpha/\beta$  and the type I IFN receptor.

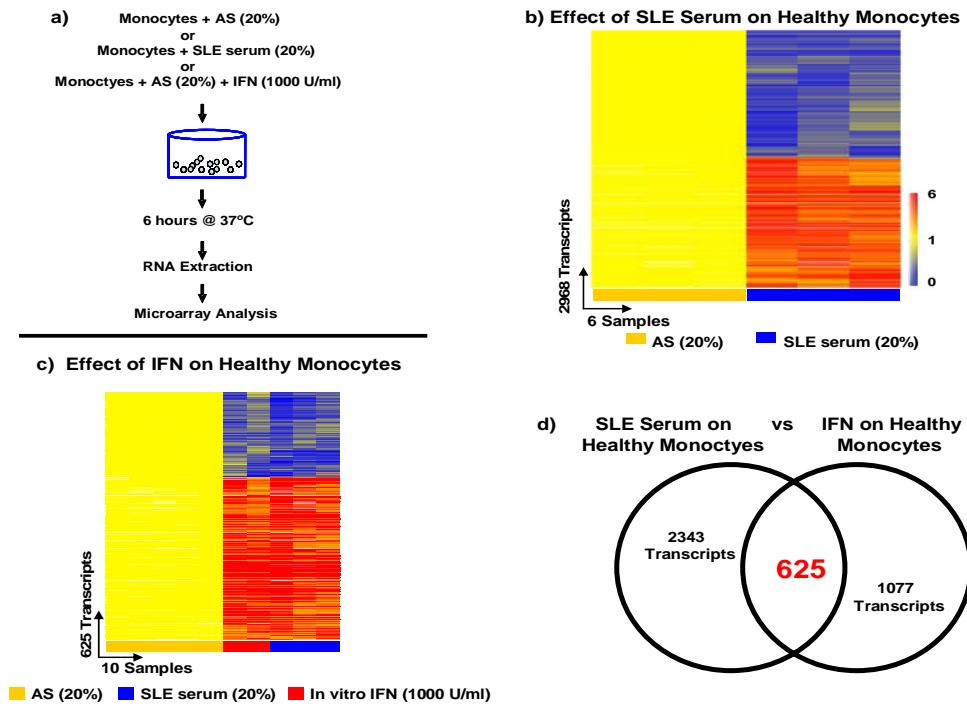

Figure 17. SLE serum induces significant changes in transcriptional program of healthy monocytes. (a) monocytes from normal donors incubated with sera from newly diagnosed SLE patients (20%) as well as with 1000U/ml of IFNa2b to study the effect on normal monocytes. (b) SLE serum induces 2968 transcripts in normal monocytes compared to autologous serum. (c) & (d) 625/2968 transcripts induced by SLE serum regulated by type-I IFN.

Comparing the gene lists derived from exposing healthy monocytes to either SLE serum or IFN- $\alpha$  for 6 hr in vitro disclosed 625 common transcripts (~20% of all SLE serum-induced genes) (Figure 17c). Of these, less than 1/3 (194 transcripts) were equally dysregulated in freshly isolated blood SLE monocytes (Figure 19 a and b). Furthermore, the expression of only half of these transcripts (115/194) was significantly blocked by preincubating SLE serum with neutralizing antibodies against both IFN $\alpha/\beta$  and the type I IFN receptor (Figure 19 c).

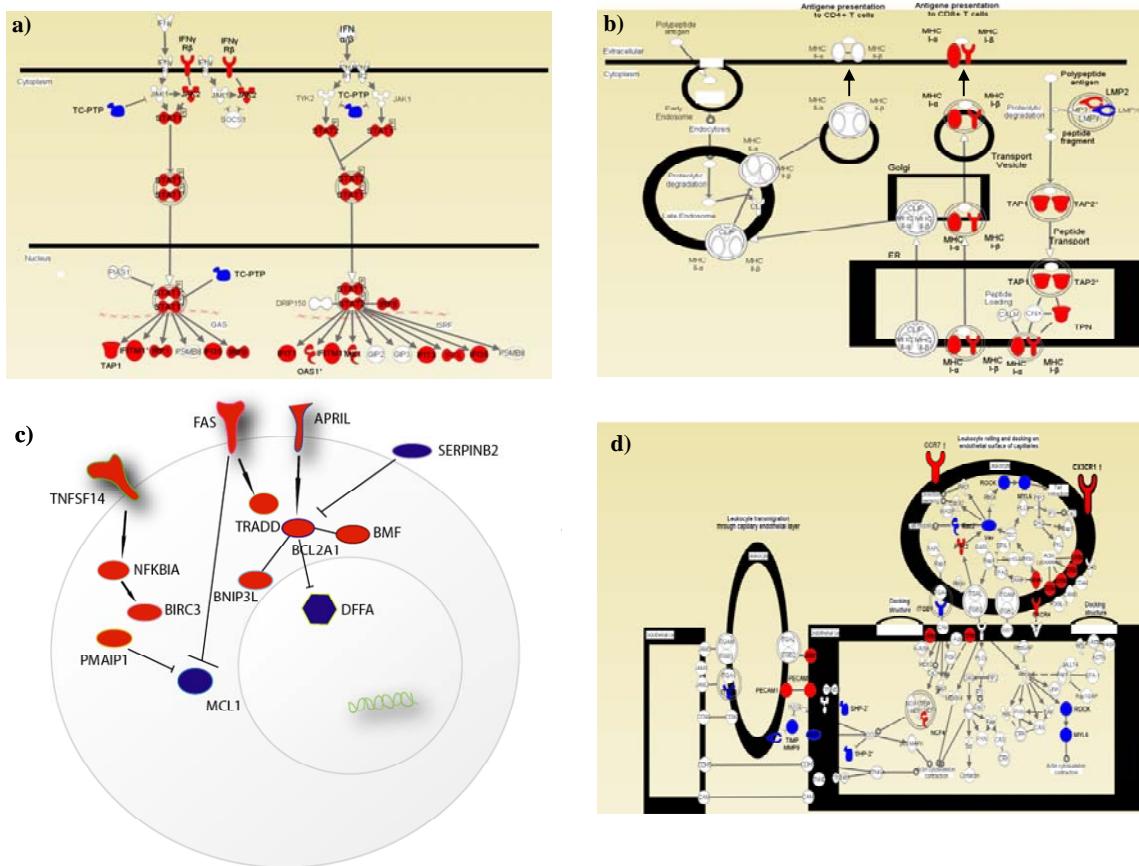

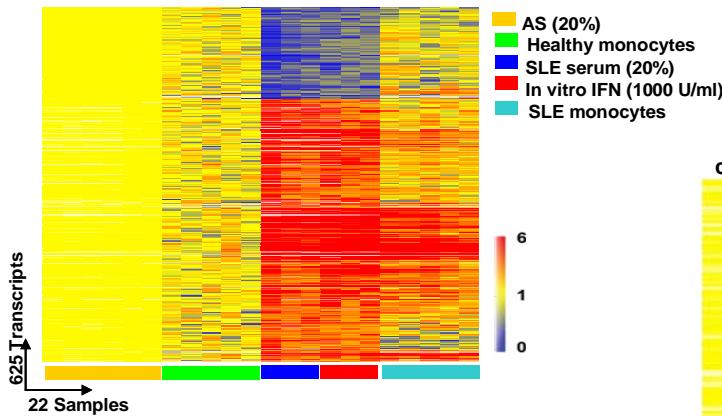

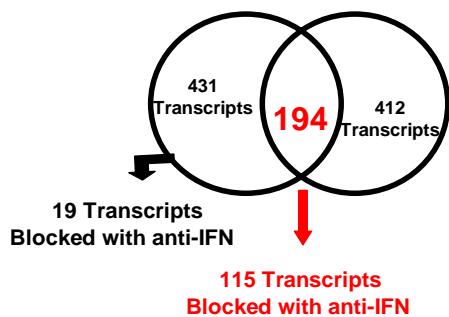

Figure 18. Pathways represented by genes induced by SLE serum in healthy monocytes. Genes involved in (a) type I IFN signaling, (b) antigen presentation, (c) apoptosis, and (d) extravasation and migration. Red color represent overexpression and blue color represent down regulation of particular molecule in ex vivo SLE monocytes.

Thus, exposure to SLE serum induces significant changes in the transcriptional program of healthy monocytes. Only a fraction of these changes, however, is also found dysregulated in the blood monocytes from SLE patients and can be attributed to type-I IFN effects.

a) Comparison Between SLE Serum or IFN on Healthy Monocytes and Ex-vivo SLE Monocytes

b) Number of Transcripts Blocked by Anti-IFN

c) Antibody Blocking Experiments

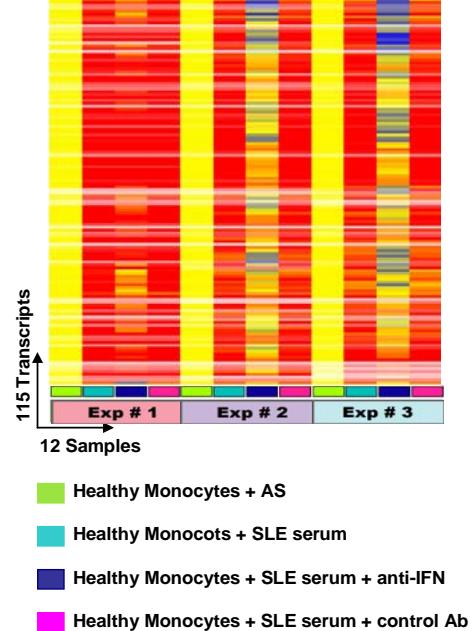

Figure 19. Comparison between SLE serum or IFN on healthy monocytes and ex vivo SLE monocytes  
a) There are 625 common transcripts expressed between healthy monocytes exposed to SLE serum or IFN-alpha for 6 hours, but only a fraction of these are expressed in freshly isolated SLE monocytes; (b) Out of 625 transcripts induced by SLE serum and regulated by type I IFN, only 194 transcripts are shared with those induced by IFN on monocytes; c) Only 115 of those transcripts can be blocked with pre-incubating SLE serum with antibody against IFNa/β and the type I IFN receptor.

*Reconciling In Vivo and In Vitro Data: SLE Serum Induces the Expression of Chemokine Receptors that Explain the Acquisition of DC Function by SLE Monocytes and Their Migration to Secondary Lymphoid Organs*

Thus far our studies have provided little evidence that ex-vivo SLE blood monocyte in fact express DC-related molecules. They also revealed little overlap between the transcriptional programs of ex vivo SLE blood monocytes and healthy monocytes incubated with SLE serum. Among the molecules, however, that were induced in vitro by exposure to IFN-alpha and/or SLE serum we found two chemokine receptors, CCR7 and CX3CR1, which could reconcile our initial hypothesis and our experimental results.

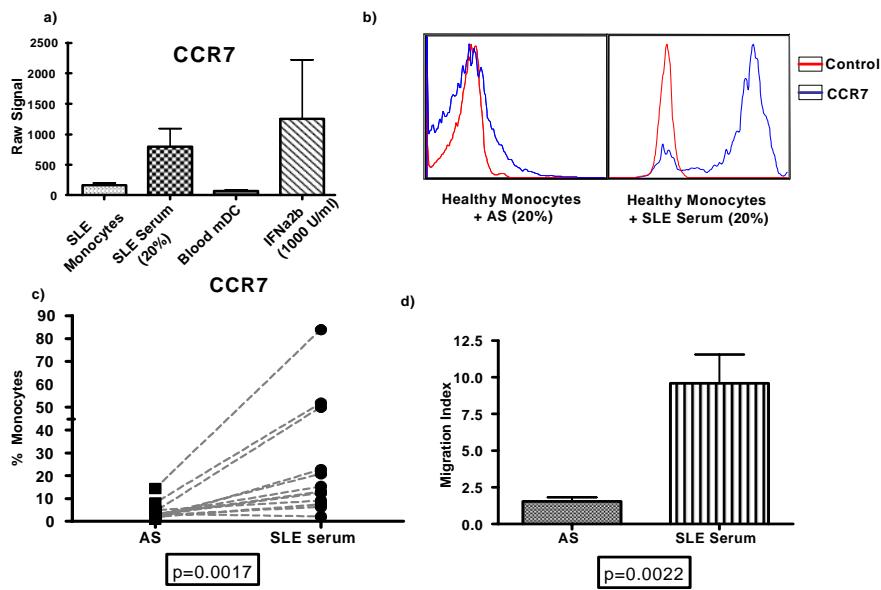

Figure 20. SLE serum induces functional chemokine receptor CCR7 at both the RNA and protein level. (a) SLE serum induce CCR7 transcript at RNA level which is dependent on the presence of type-I IFN in serum. (b) Chemokine receptor CCR7 expression at the protein level upon exposure to SLE serum for 24 hours. (c) Expression of CCR7 is significantly different on monocytes cultured with SLE serum compared to autologous serum (n= 12 experiments). (d) Chemokine receptor CCR7 expressed on monocytes is functional as evidenced by the fact that its ligand, CCL19, induces *in vitro* migration in a transmigration assay (n= 6 experiments).

CCR7 is expressed on mature DCs and T cells and is a homing receptor for these cells to migrate to the lymph node where its ligands (CCL19 and CCL21) are expressed (Dieu and others 1998; Saeki and others 1999; Sallusto and others 1999). CX3CR1 is a chemokine receptor for fractalkine, which is normally expressed in inflamed tissues. It has recently been shown that two subsets of monocytes can be classified based on expression of this receptor: (1) CX3CR1<sup>lo</sup> CD14<sup>++</sup>CD16<sup>-</sup> monocytes, and (2) CX3CR1<sup>hi</sup> CD14<sup>lo</sup> CD16<sup>+</sup> monocytes (Geissmann and others 2003). We surmised that in the initial stages of SLE, monocyte exposure to type I IFN and/or other components of SLE serum would efficiently upregulate these receptors and induce their migration to either lymph nodes or peripheral inflamed tissues. There, monocyte contact with T cells would induce the upregulation of molecules involved in antigen presentation (i.e. HLA class II) and

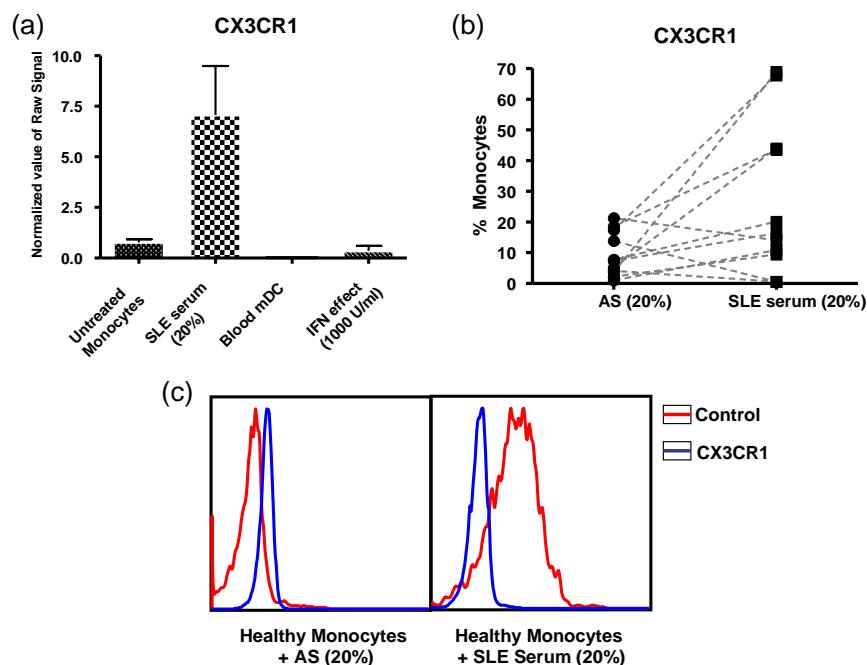

Figure 21. SLE serum induces expression of the fractalkine receptor, CX3CR1, at both the RNA and protein level. (a) SLE serum induces CX3CR1 transcript expression at the RNA level which is independent of the presence of type-I IFN in the serum. (b) The fractalkine receptor CX3CR1 expression at the protein level is dependent upon exposure to SLE serum for 24 hours. (c) After incubation for 24 hours, the majority of SLE sera induce CX3CR1 expression on the surface of healthy monocytes compared to autologous serum (n= 10 experiments).

give rise to an immune/autoimmune response. To address our hypothesis, we wanted to check 1) if these chemokine receptors were also upregulated at the protein level upon exposure to SLE serum, 2) if their upregulation would correlate with functional activity.

To address the first question, we performed flow cytometry on healthy monocytes exposed for 24 hr in culture to either autologous serum or the serum of 12 pediatric SLE patients. As CCR7 was upregulated at the transcriptional levels by both IFN-alpha and SLE serum, we found indeed a significant upregulation of the corresponding protein upon exposure to SLE serum ( $p=0.0017$ , Figure 20 a-c). Furthermore, we devised transwell experiments to follow the migration of healthy monocytes incubated with SLE serum towards one of the two CCR7 ligands. The results of these experiments supported that overexpression of CCR7 on the surface of monocytes did lead to their more efficient migration towards CCL19 (Figure 20d).

As opposed to CCR7, expression of CX3CR1 at the transcriptional level was only induced by SLE serum but not by exposure to IFN- $\alpha$  in vitro (Figure 21a). Exposure to a fraction of the SLE patient sera (8/12) did upregulate the expression of CX3CR1 at the protein level on healthy monocytes (Figure 21b and c). These results, however, did not reach statistical significance.

## CHAPTER FOUR

### *Discussion*

This project was designed to understand the alterations leading to monocyte differentiation and acquisition of DC function in SLE patients. Although monocytes represent a major source of precursor DCs, when freshly isolated from healthy human blood these cells do not behave as efficient antigen presenting cells. Blood monocytes from SLE patients however act as mDCs, and exposure of normal monocytes to SLE serum, but not to FCS, results in the generation of DCs (Blanco and others 2001).

Blood monocytes are quite heterogenous (Passlick and others 1989). The differential expression of CD14 and CD16 (also known as Fc $\gamma$ RIII) was first used to define two major subsets in peripheral blood: the “classical” CD14<sup>high</sup>CD16<sup>-</sup> monocytes, typically representing up to 95% of the monocytes in a healthy individual, and the “non-classical” CD14<sup>low</sup>CD16<sup>+</sup> monocytes comprising the remaining fraction of monocytes (Passlick and others 1989; Ziegler-Heitbrock and others 1993). These subsets differ in many respects, including adhesion molecule and chemokine receptor (CCR) expression. CD14<sup>high</sup>CD16<sup>-</sup> monocytes express CCR2, CD62L (L-Selectin) and FC $\gamma$ RI (CD64), whereas CD14<sup>lo</sup>CD16<sup>+</sup> monocytes lack CCR2, and have higher levels of MHC-II and FC $\gamma$ RII (CD32) (Ziegler-Heitbrock and others 1993) (Geissmann and others 2003; Gordon and Taylor 2005). CD14<sup>lo</sup> CD16<sup>+</sup> monocytes are also thought to be more mature, macrophage like, and are regarded as pro-inflammatory because upon LPS stimulation produce more TNF- $\alpha$  than CD14<sup>high</sup> CD16<sup>-</sup> cells and produce little if any IL-10 (Belge

and others 2002). Both subsets express the receptor for fractalkine, CX<sub>3</sub>CR1, but CD14<sup>lo</sup>CD16<sup>+</sup> monocytes characteristically express higher levels (Ancuta and others 2003; Geissmann and others 2003). Considerable heterogeneity is known to exist in the minor CD16<sup>+</sup> monocyte fraction, as an “intermediate” population of monocytes that is CD14<sup>high</sup> (as opposed to CD14<sup>lo</sup>) and CD16<sup>+</sup> differentiates in vitro differently than CD14<sup>lo</sup>CD16<sup>+</sup> monocytes (Grage-Griebenow and others 2001b).

Interest in CD16<sup>+</sup> monocytes has been promoted by observations that this subset is elevated in blood during inflammatory conditions such as HIV dementia (Pulliam and others 1997), atherosclerosis(Schlitt and others 2004), rheumatoid arthritis (Baeten and others 2000), and cancer (Saleh and others 1995). In a number of studies, CD16<sup>+</sup> monocytes have been called inflammatory monocytes. However, this designation awaits a functional confirmation.

Several studies have analyzed the differentiation of human monocyte subsets in vitro and these studies showed in some cases a predisposition of CD16<sup>+</sup> monocytes to differentiate into antigen-presenting DCs (Grage-Griebenow and others 2001b; Randolph and others 2002). The extent to which human monocyte subsets differentiate into DCs in vivo is indeed too complex to predict, as both the phenotype of the cultured monocytes and factors present in the in vitro culture are expected to have a strong influence on the differentiation. For instance, CD14<sup>high</sup>CD16<sup>-</sup> monocytes differentiate into Langerhans cells, the typical epidermal DC population, with potent antigen-presentation functions in a modified tissue-engineered model of human epidermal equivalents (Schaerli and others 2005). However, in the absence of the epidermal environment, but in the presence of

vascular endothelial cells, CD16<sup>+</sup> monocytes are more prone to become DCs (Randolph and others 2002).

The most popular model to study monocyte-derived DCs is to culture blood monocytes of either subset in the presence of GM-CSF and IL-4 (Sallusto and Lanzavecchia 1994) or other related cytokine cocktails (Piemonti and others 1995). It is not clear however whether GM-CSF/IL-4-treated monocyte-derived DCs have true counterparts *in vivo*. Thus, whereas the study of IL-4/GM-CSF-cultured monocyte-derived DCs is useful for studying DC biology, it is important to keep in mind that the pathway of differentiation that leads to the generation of these cells may not be recapitulated *in vivo*.

An important observation from earlier work at our Institute was that blood monocytes from a fraction of pediatric SLE patients function as DCs. We surmised that studying the phenotype of monocytes from the blood of newly diagnosed, active and previously untreated SLE patients might help us better define the DC characteristics of these cells. Thus, we used flow cytometry to characterize 1) the monocyte subpopulation distribution in pediatric SLE patients and healthy children, 2) the expression of molecules that might explain the acquisition of DC function by SLE monocytes. Using the conventional scheme of CD14 and CD16 expression, a complex picture of monocyte population distribution emerged. Indeed, 4 discrete populations could be recognized in the majority of blood samples: 1) CD14<sup>high</sup> CD16- CD64+ CD62L+ HLA-DR<sup>low</sup>, 2) CD14<sup>high</sup> CD16+ CD64+ CD62L+ HLA-DR<sup>high</sup>, 3) CD14<sup>low</sup> CD16+ CD64- CD62L- HLA-DR<sup>high</sup> and 4) CD14<sup>low</sup> CD16- CD64- CD62L- HLA-DR<sup>low</sup>. Furthermore, the complexity could be even higher, as a fifth population characterized by very high

expression of CD14 and negative CD16 surface expression could be identified in some healthy children. According to this phenotypic scheme, pediatric SLE patients displayed an expansion of CD14<sup>high</sup> CD16+ cells ( $p=0.01$ ) while the distribution of the remaining populations did not differ from controls.

CD14<sup>high</sup> CD16+ monocytes most likely correspond to a minor subset of CD64(+) / 16(+) cells which were described in 2001 as being unique in combining typical DC and monocyte characteristics (Grage-Griebenow and others 2001b). These are high IL-12 production, high accessory capacity for antigen- or allogen-activated lymphocytes, and high expression of HLA-DR, CD86, and CD11c. More recently, the same group reported that upon LPS stimulation CD14<sup>high</sup> CD16+ monocytes produce significantly more IL-10 than CD14<sup>high</sup> CD16- and CD14<sup>low</sup> CD16+ monocytes at the protein and mRNA levels. In addition, CD14<sup>high</sup> CD16+ cells produce significantly more IL-10 than their CD14<sup>low</sup> CD16+ counterparts when activated with *S. aureus* or zymosan. Thus, CD14<sup>high</sup> CD16+ monocytes seem to be functionally different from CD14<sup>low</sup> CD16+ monocytes and might be considered anti-inflammatory at least in healthy individuals (Skrzeczynska-Moncznik and others 2008). Whether the expanded population that we observe in SLE blood is equivalent to this “anti-inflammatory” monocyte subset requires however further study. Indeed, as we will review below, exposure of healthy monocytes to IFN-alpha and SLE serum in vitro induces significant changes in some of the markers that are used to define monocyte subpopulations. CD14, CD64 and CD16 expression for example change dramatically under these conditions. Whether these in vitro changes represent true monocyte population shifts and how do these changes correlate with the expansion or contraction of monocyte population *in vivo* need to be further addressed.

Besides the surface markers that define known human monocyte subpopulations, we performed a phenotypic analysis of molecules known to be upregulated as immature DCs differentiate and acquire DC function. To our surprise, most of these molecules were similarly expressed in cells from healthy children and SLE patients. The two main exceptions included a mild upregulation of CCR7 and a significant down-regulation of HLA-DR molecules both especially within the CD14<sup>high</sup> CD16- monocyte fraction from SLE patients.

The fact that none of the classic surface molecules involved in antigen presentation (i.e. HLA-DR, CD80, CD86) or in monocyte differentiation into DC (i.e. CD83) were upregulated in SLE blood monocytes led us to perform a more global analysis, i.e. gene expression profiling, to identify possible differences between healthy children and patient cells. Indeed, blood monocytes from 5 active, newly diagnosed patients who had never received oral or IV medications differentially expressed 1,629 transcripts. As PBMCs from >90% SLE patients express a type I IFN signature (Bennett and others 2003), we surmised that a large proportion of the genes found differentially expressed in SLE monocytes might be IFN-regulated. To identify these genes, we first exposed monocytes from 2 healthy donors to type I IFN in vitro and found that >37% of the transcripts dysregulated in SLE monocytes were induced by type I IFN in vitro. The remaining transcripts were not considered to be type I IFN regulated as either they were not up or down-regulated in culture at any time point during the 72hr of exposure to IFN-alpha, or their fold expression changed but their raw expression value in vitro did not reach the value that we selected as threshold to document true changes in expression. This, therefore, most likely represents a significant underestimation of the effects of IFN-

alpha. Indeed, many factors, may affect the transcriptional activity of monocytes in culture, and therefore only an *in vivo* experiment (i.e. administration of IFN alpha to a healthy volunteers with subsequent longitudinal follow up) would allow us to fully address this question.

Within the transcripts that we selected as *bona fide* type I IFN-regulated, we found dysregulation of most of the genes that previous work from our laboratory using PBMCs from SLE patients had identified as components of the IFN-signature (Bennett and others 2003). Significantly upregulated genes encoded apoptosis-inducing molecules such as TRAIL and FAS; adhesion molecules such as sialoadhesin, a monocyte/macrophage specific lectin, SLAMFM7 (CRACC), a member of the CD2 family of cell surface receptors implicated in the activation of NK cell-mediated cytotoxicity, ITGB7, a receptor for fibronectin, MADCAM1 and VCAM1, and claudin 23, a molecule that plays a major role in tight junction-specific obliteration of the intercellular space; ubiquitination such as culin 1, an essential component of the SCF (SKP1-CUL1-F-box protein) E3 ubiquitin ligase complex, which mediates the ubiquitination of proteins involved in cell cycle progression, signal transduction and transcription and, ISG15 and its deconjugating protease USP18; chemokines and chemokine receptors such as CXCL10 (IP10), CCR1, CCR5, CCL2 (MCP1) and CCL8 (MCP2); and Fc receptors such as CD64 (Fc $\gamma$ RIA), which as described above is normally expressed on CD14<sup>high</sup> monocytes. Within the list of genes that we could not formally ascribe as IFN alpha-regulated (in part due to the limitations of the *in vitro* experiments), there was a remarkable down-regulation of ribosomal protein- and HLA class II-encoding transcripts.

To identify genes which could explain the DC characteristics of SLE monocytes, we sought to compare the transcriptional profile of SLE blood monocytes with those of blood mDCs. Thus, mDCs were sorted from five healthy individuals and their transcriptional programs were compared to those of blood CD14+ monocytes isolated from the same donors. These studies showed that healthy blood mDCs differentially express >2,000 transcripts compared to monocytes. Among them, and as expected, HLA class II genes were significantly upregulated and CD14 was downregulated. None of the known co-stimulatory molecules that become upregulated during DC maturation (i.e. CD80, CD86 etc.) were differentially expressed at the transcriptional level however in healthy blood mDCs. Among Toll-like receptors (TLRs), TLR2, 4, 5 and 8 were significantly down-regulated while TLR-3 and 10 were upregulated. We found that a very small fraction of “mDC transcripts” were similarly expressed in blood SLE monocytes. This is not entirely surprising though, as blood mDC precursors may represent a totally independent DC subpopulation compared to DCs generated from monocyte precursors. None of the proteins encoded by the overlapping genes in these two cell types could however explain the DC function of SLE monocytes. Thus, we decided to explore the possibility that contact with T cells might be required in order for SLE monocytes to acquire an antigen-presenting transcriptional program and/or phenotype.

As previously published (Blanco and others 2001), not every SLE patient displays blood monocytes able to induce alloreactive CD4+ T cell proliferation. Thus, we screened SLE monocytes from a group of SLE patients in standard alloreactions and classified samples based on either capacity to induce CD4 T cell proliferation. The transcriptional profiles of MLR+ and MLR- monocytes disclosed 265 transcripts

differentially regulated in these two groups. All SLE monocyte samples which induced CD4+ T cell proliferation upregulated MHC class II transcripts after 6 hr of culture with T cells at similar levels as blood mDC. Other MLR+ monocyte upregulated transcripts encoded innate immunity molecules such as IL-1b, KCNJ15, a potassium rectifier channel which follows the transcription pattern of IL-1b (Pascual and others 2005), MARCO, a receptor involved in actin cytoskeleton rearrangements and down-regulation of antigen uptake function during DC maturation (Pikkarainen and others 1999), and CXCL10, a ligand for CXCR3 that is induced by type I and type II IFN and may play a key role in IFN- $\gamma$  mediated responses (Piali and others 1998). This microarray data was further confirmed at two levels: first, cell surface staining of SLE monocytes after 48-hours in culture with CD4 T cells showed that the expression level of class II molecules correlated with the capacity of these cells to induce CD4+ T cell proliferation; second, cytokines levels in the supernatant of the monocyte-T cell cultures disclosed increased levels of IL-1b in 3/4 cultures inducing CD4 T cell proliferation. IL6, which may be induced by IL-1b, was elevated in the same cultures. Thus, these studies suggest that blood SLE monocytes require signals derived from T cells in order to acquire DC function. Additionally, they point towards an important role for innate immunity receptors and/or cytokines, i.e. MARCO and IL-1b/IL-6, in conferring antigen-presenting capacity to monocytes from SLE patients. The capacity of activated T cells to induce IL-1 production in monocytes has been reported as an antigen independent pathway. Indeed, IL-1 could be induced in third-party HLA-DR nonspecific monocytes in cocultures of alloreactive T cell clones or blasts and HLA-DR-specific DCs. The induction was independent of a soluble factor, since dendritic cells and T blasts placed in a chamber

separate from third-party monocytes by a semipermeable membrane did not induce monocyte IL-1. These results suggest that a cell contact mechanism rather than an IL-1-inducing factor leads to IL-1 production (Bhardwaj and others 1988). How the type I IFN-rich environment of SLE blood predisposes monocytes to respond to T cell signals and/or to produce the cytokines that we describe above remain to be elucidated.

An important observation from earlier work at our Institute was that the addition of SLE serum to healthy monocytes induced the differentiation of these cells into DCs (Blanco and others 2001). This effect could be reproduced by adding IFN-alpha to healthy human serum, but not to FCS. Thus, one or several components of human serum seem to be necessary to facilitate the DC-poietin activity of type I IFN. We surmised that by studying the transcriptional program induced by SLE serum on healthy monocytes we might gain insight into these putative serum factor(s). This approach might also help us recapitulate the events responsible for the skewing of monocytes into DCs during the initial stages of SLE. We found that incubation with serum from active, untreated SLE patients induced the differential expression of ~3,000 transcripts on healthy monocytes. Functional characterization of these transcripts revealed a significant upregulation of genes involved in biological pathways such as apoptosis, adhesion, chemotaxis, pattern recognition receptors, Fc receptors, RNA and protein modification, signaling and transcription. All these categories included both well known type I IFN-inducible as well as type I IFN independent genes. The induction of pro-apoptotic genes may explain the death-inducing capacity of SLE serum, which seems to be at least partially independent of the effects of IFN alpha. Indeed, while monocytes remain alive in culture for up to 3 days when exposed to IFN alpha in the presence of human serum, SLE serum exposed

monocytes do not survive more than 24 hr in vitro (data not shown). This is not surprising, as SLE serum induces significant transcriptional changes in apoptosis inducing molecules many of which are IFN-alpha independent. Among genes with well defined immune function, SLE serum also upregulates innate immunity receptors such as NOD2, TLR7 and TLR8. This might cause SLE monocytes to become hyper-responsive upon interaction with pathogens and/or immune complexes containing nucleic acids (Vallin and others 1999b). Indeed, SLE serum also induces the upregulation of transcription of Fc $\gamma$  receptors, especially Fc $\gamma$ RIa, Fc $\gamma$ RIIIa. Among genes involved in signal transduction, SLE serum (and IFN-alpha as well) upregulates the transcription of IRF-5, a candidate susceptibility gene for SLE (Graham and others 2006; Sigurdsson and others 2005). SLE serum also induced the upregulation of genes encoding molecules involved in nucleosome and chromatin modification, RNA processing and ubiquination. It did not upregulate HLA class II-encoding transcripts but genes encoding molecules involved in HLA class I transport, especially TAP1, TAP2 and Tapasin. Finally, among the most differentially regulated genes we found chemokine and chemokine receptors such as CXCL10, CXCR4 and CCR7.

To our surprise, only a minority of SLE serum-induced transcripts (~8%) overlapped with the transcripts found dysregulated in ex-vivo SLE blood monocytes. Of these common genes, less than 1/3 (194 transcripts) were induced by IFN alpha. Furthermore, the expression of only half of these transcripts (115/194) was significantly blocked by preincubating SLE serum with neutralizing antibodies against both IFN $\alpha/\beta$  and the type I IFN receptor. Thus, exposure to SLE serum induces significant changes in the transcriptional program of healthy monocytes. Only a fraction of these changes,

however, is also found dysregulated in the blood monocytes from SLE patients and can be attributed to type-I IFN effects. Caution should however be applied to the interpretation of these studies. First, our selection criteria for considering a transcript to be IFN-regulated in vitro were quite stringent. Second, we only tested the transcriptional program induced by in vitro exposure to recombinant IFN-alpha 2b. It is very likely that other closely related type I IFN molecules, including different alpha subclasses, do give rise to different transcriptional changes. Finally, even though we tried to neutralize all possible type I IFN molecules by adding anti-type I IFN receptor antibodies to SLE serum, we did not attempt to block the IFN- $\lambda$  receptor which also gives rise to overlapping yet unique downstream signaling events. Finally, it has been proposed that an IFN signature may be triggered in monocytes through activation of receptors which induce STAT-1 phosphorylation independently of type I IFN receptor engagement. In particular, signals delivered via both Fc $\gamma$ RIIIA and Fc $\gamma$ RIIA seem to induce such transcriptional program (Dhopakar and others 2007). Immune complexes from SLE serum could therefore be responsible for this type of transcriptional response. Whether in fact the CD16+ blood monocyte fraction is more likely to express the IFN signature in healthy subjects and/or SLE patients remains to be clarified.

Our studies so far provided little evidence to support that ex-vivo SLE blood monocyte express DC-related molecules. They also revealed little overlap between the transcriptional programs of ex vivo SLE blood monocytes and healthy monocytes incubated with SLE serum. Furthermore, not all the transcriptional changes induced by incubating healthy monocytes with SLE serum were translated into true phenotypic changes at the protein level. For example, surface staining of monocytes after 24 hr

incubation with SLE serum revealed profound down-regulation of CD16 and mild downregulation of CD64 even though both transcripts were upregulated at the RNA level. This could be explained however by receptor occupancy by serum Ig and/or Immune complexes. As our laboratory had shown before, we confirmed the downregulation by SLE serum of CD14 and the upregulation of CD83, a bona fide DC maturation marker, on the cell fraction that downregulates CD14 in vitro (originally CD14<sup>high</sup> monocytes, data not shown). On the same fraction, we observed a significant upregulation of CCR7. This chemokine receptor is expressed on mature DCs and T cells and is a homing receptor for these cells to migrate to the lymph nodes where its ligands (CCL19 and CCL21) are expressed (Willimann and others 1998). The SLE serum induced in vitro upregulation of CCR7 was indeed accompanied by a gain of function, as migration studies showed that healthy monocytes incubated with SLE serum did migrate more efficiently towards CCL19. CX3CR1 is a chemokine receptor for fractalkine, which is normally expressed in inflamed tissues. This receptor is preferentially expressed on CD14<sup>lo</sup> CD16<sup>+</sup> monocytes (Geissmann and others 2003). As opposed to CCR7, expression of CX3CR1 at the transcriptional level was only induced by SLE serum but not by exposure to IFN-alpha in vitro. Exposure to the majority of the SLE patient sera tested did upregulate the expression of CX3CR1 at the protein level on healthy monocytes.

We surmise that in the initial stages of SLE, monocyte exposure to type I IFN and/or other components of SLE serum would efficiently upregulate these receptors and subsequently induce the migration monocytes to either lymph nodes or peripheral inflamed tissues. There, our work supports a model where monocyte contact with T cells

would induce the upregulation of molecules involved in antigen presentation (i.e. HLA class II) and give rise to an immune/autoimmune response (figure 22). Indeed, what is left in the blood of patients with ongoing disease might represent recently-emigrated monocyte bone marrow precursors and/or exhausted cells that are not able to efficiently upregulate in vivo the receptors within pathways that mediate their recruitment into lymphoid and/or inflamed tissues. As we start to identify some of these pathways, we might be able to better dissect the important events underlying monocyte and DC alterations in patients with SLE. This might lead to the identification of efficient and safe therapeutic targets (figure 23).

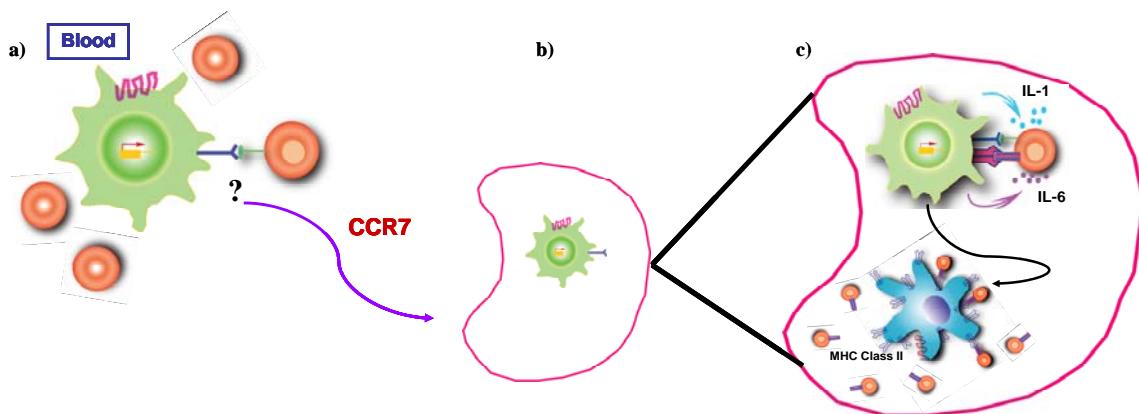

Figure 22. How lupus monocytes encounter T cells? SLE monocytes circulating in the blood express CCR7 due to type I IFN presence in SLE patients. They migrate to secondary lymphoid tissues where they come in contact with T cells, secrete IL-1 and IL-6 and induce expansion of T cells.

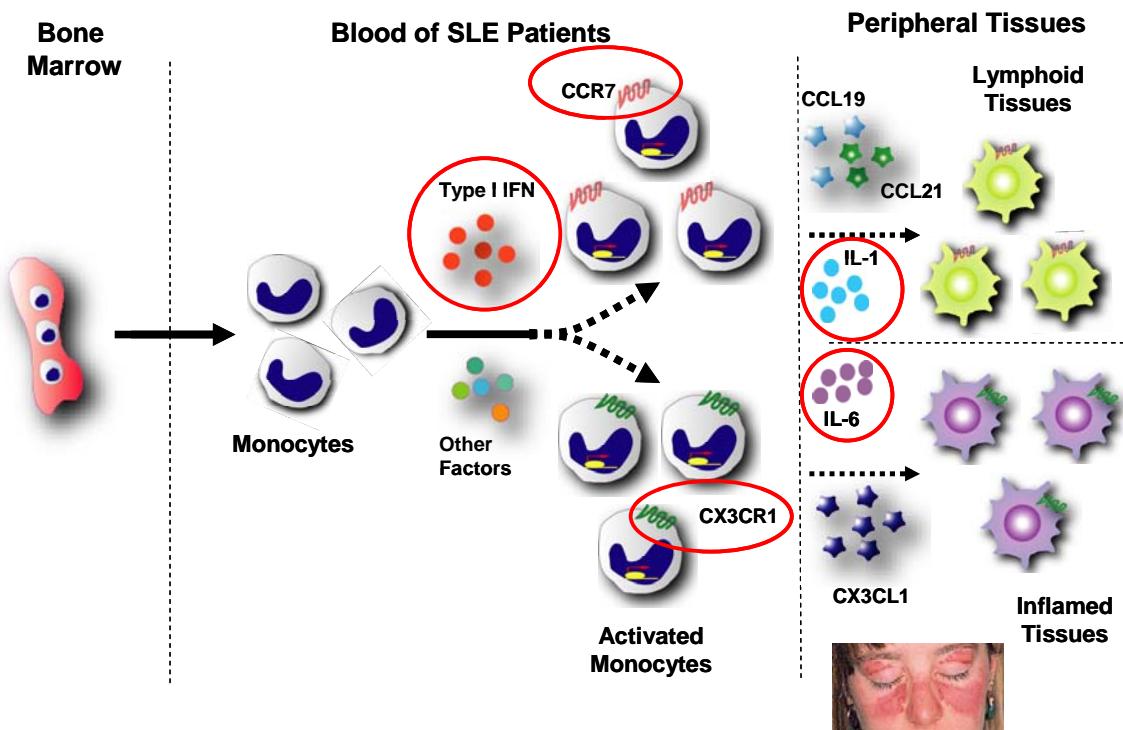

Figure 23. Potential therapeutic targets to treat SLE. Newly emigrated monocytes from bone marrow upon encountering type I IFNs or other factors in SLE microenvironment express CCR7 and/or CX3CR1 on their surface and migrated to lymphoid tissues or inflamed tissues where they may secrete IL-1 and IL-6. Red circles point at molecules of potential intervention to treat SLE.
